

# *Hele–Shaw Limit for a System of Two Reaction-(Cross-)Diffusion Equations for Living Tissues*

FEDERICA BUBBA, BENOÎT PERTHAME, CAMILLE POUCHOL  & MARKUS SCHMIDTCHEN

*Communicated by P.-L. LIONS*

## Abstract

Multiphase mechanical models are now commonly used to describe living tissues including tumour growth. The specific model we study here consists of two equations of mixed parabolic and hyperbolic type which extend the standard compressible porous medium equation, including cross-reaction terms. We study the incompressible limit, when the pressure becomes stiff, which generates a free boundary problem. We establish the complementarity relation and also a phase-segregation result. Several major mathematical difficulties arise in the two species case. Firstly, the system structure makes comparison principles fail. Secondly, segregation and internal layers limit the regularity available on some quantities to BV. Thirdly, the Aronson–Bénilan estimates cannot be established in our context. We are led, as it is classical, to add correction terms. This procedure requires technical manipulations based on BV estimates only valid in one space dimension. Another novelty is to establish an  $L^1$  version in place of the standard upper bound.

## 1. Introduction

Models of living tissues lead to the following evolution system that we consider in one space dimension,  $x \in \mathbb{R}$ ,  $t \geq 0$ :

$$\begin{cases} \frac{\partial n_\gamma^{(1)}}{\partial t} = \frac{\partial}{\partial x} \left( n_\gamma^{(1)} \frac{\partial p_\gamma}{\partial x} \right) + n_\gamma^{(1)} F_1(p_\gamma) + n_\gamma^{(2)} G_1(p_\gamma), \\ \frac{\partial n_\gamma^{(2)}}{\partial t} = \frac{\partial}{\partial x} \left( n_\gamma^{(2)} \frac{\partial p_\gamma}{\partial x} \right) + n_\gamma^{(1)} F_2(p_\gamma) + n_\gamma^{(2)} G_2(p_\gamma), \end{cases} \quad (1)$$

where the pressure  $p_\gamma$  is given by the law of state

$$p_\gamma := (n_\gamma)^\gamma, \quad \gamma > 1, \quad n_\gamma := n_\gamma^{(1)} + n_\gamma^{(2)}. \quad (2)$$

We equip this system with nonnegative initial data with compact support:

$$n_\gamma^{(i)}(0, x) = n_{\gamma, \text{init}}^{(i)}(x) \in L^1(\mathbb{R}), \quad i = 1, 2. \quad (3)$$

Here  $n_\gamma^{(1)}$ ,  $n_\gamma^{(2)}$  denote the population densities, while  $F_i$ ,  $G_i$  model the reaction or growth phenomena, which are assumed to depend exclusively on the pressure  $p_\gamma$  according to the observations in [8, 31]. Throughout, we will call  $G_1$  and  $F_2$  the *cross-reaction* terms.

The purpose of our analysis is to study the Hele–Shaw limit for the solutions  $n_\gamma^{(1)}$  and  $n_\gamma^{(2)}$  of system (1) and the pressure, namely their convergence when  $\gamma$  tends to  $+\infty$ . We establish both the compactness argument in order to pass to the limit in the nonlinear terms and the limiting equations satisfied by the pressure and the densities.

**Motivation and earlier works.** Compressible mechanical models such as (1) and variants have become ubiquitous in mathematical biology with applications in modelling living tissues and tumour growth, among others. In the latter instance,  $n_\gamma^{(1)}$  and  $n_\gamma^{(2)}$  represent cancer cells and quiescent or healthy cells, respectively, with different growth rates, and possible transitions from a state to the other. A question which arises here is to know whether segregation effects occur between two or more species in the absence of cross-reaction terms [5, 9, 30].

Models of this type have been attracting attention for many decades, starting with epidemiological models, cf. [7]. In its current form, but in the absence of any reaction terms, Eq. (1) was proposed in the seminal paper by GURTIN and PIPKIN [13] and an existence and segregation theory was given in a series of papers, see [3] and the references therein. Reaction terms were added and studied later, the existence and segregation of solutions was established; see [2, 4].

Quite recently, the no-vacuum assumption on the initial data could be removed and thus the existence of (segregated) solutions on bounded intervals for a wider class of initial data could be shown using tools from optimal transportation; see [9]. A little later, another existence result in higher dimensions was proposed in [14] by establishing strong compactness of the pressure gradient using a Aronson–Bénilan type estimate without commenting on segregation results which are, however, expected to be true; see the general argument in Section 5.

Taking the incompressible limit  $\gamma \rightarrow +\infty$  has attracted attention in the past in the one-species case, say, if  $n_\gamma^{(2)} = 0$ ,

$$\frac{\partial n_\gamma}{\partial t} = \frac{\partial}{\partial x} \left( n_\gamma \frac{\partial p_\gamma}{\partial x} \right) + n_\gamma F_1(p_\gamma).$$

The motivation for such asymptotics in cancer modelling is to bridge the gap between the mechanical, compressible model, (1), and a commonly used different class of incompressible models, see the survey papers [20, 32]. A major mathematical interest is the relation to geometric models. These are the so-called Hele–Shaw models, where the evolution of the tumour is described through the movement of the free boundary of a domain  $\Omega(t)$  occupied by the tumour. In these models, the total cell density can take up only the values 0 and 1, where 1 corresponds to the tumour.

Such results have been obtained successively in [29] and followed by several others [15, 27, 28], for a different pressure law. The typical result is that the pressure  $p_\gamma$  and the density  $n_\gamma$  converge strongly to the limits  $p_\infty, n_\infty$  that satisfy the so-called *complementarity relation* (in the distributional sense):

$$p_\infty \left( \frac{\partial^2 p_\infty}{\partial x^2} + F_1(p_\infty) \right) = 0, \tag{4}$$

together with the weak form of the Hele–Shaw free boundary problem

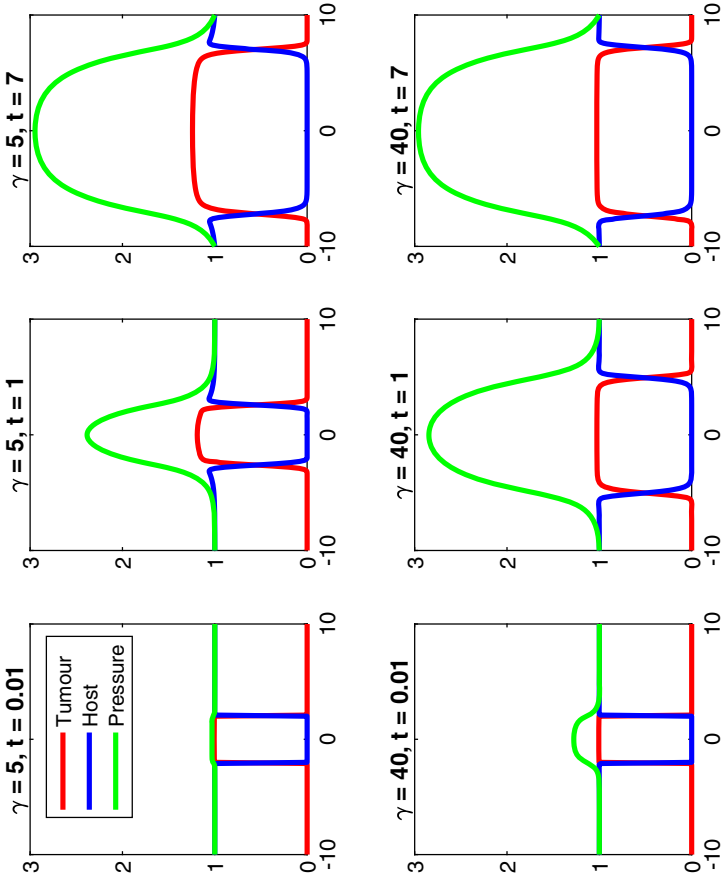

$$\begin{cases} \frac{\partial n_\infty}{\partial t} = \frac{\partial}{\partial x} \left( n_\infty \frac{\partial p_\infty}{\partial x} \right) + n_\infty F_1(p_\infty), \\ p_\infty(1 - n_\infty) = 0. \end{cases} \tag{5}$$

A remarkable property is the uniqueness of the solution despite the weak relation between  $n_\infty$  and  $p_\infty$ . The compressible model and the Hele–Shaw description of a tumour are linked through the set  $\Omega(t) := \{x, p_\infty(t, x) > 0\}$  which coincides a.e. with the set  $\{n_\infty = 1\}$  and may therefore be considered as the tumour; see, e.g., [25].

Notice that the above approach to the incompressible limit is not the only one. Methods based on viscosity solutions are also well-established for these growth problems [16–18]. One can also mention that the incompressible limit is also called “congestion” in crowd-motion, and a recent approach is based on optimal transportation arguments [22–24].

The evolution of solutions to system (1) and the corresponding pressure are shown, for two values of  $\gamma$ , in Fig. 1. The reaction terms are  $F_1(p) = (1 - \frac{p}{K})$ , with  $K = 3$ ,  $G_2(p) = (1 - p)$  and  $G_1(p) = F_2(p) = (1 - p)_+$ . In this case,  $n_\gamma^{(1)}$  (tumour cells, red line) is the population with the greatest carrying capacity  $K$  and it invades the other one (host cells, blue line). In Fig. 2, the parameters are  $\gamma = 5$ ,  $F_1(p) = 2(1 - p)$  and  $G_2(p) = (1 - p)$ , there are no cross-reaction terms, and we let the total density vanish in some parts of the domain. The two densities are initially segregated and remain so (see [9] and Section 5).

**Specific difficulties.** Two kinds of discontinuities of different natures arise in the two cell population model. The first type is on the total cell density  $n_\infty$ , as in the single cell type model, generating a free boundary moving with the Stefan condition  $v = -\frac{\partial p_\infty}{\partial x}$ . The second type are internal jumps on  $n_\infty^{(i)}$  keeping  $n_\infty$  continuous and thus only bounded variation is expected; cf. e.g., [4, 9] and references therein. They are a major hurdle because they strongly constrain the possible *a priori* estimates. Also, they are naturally related to the important segregation property mentioned earlier. Note that the paper [12], for a different pressure law, provides a deep understanding of the internal layer dynamics in the incompressible limit but only when the initial data is assumed to be initially segregated with a single contact point. This has the advantage of directly applying regularity results of [2]. In the present work, we do not rely on this type of regularity. Our analysis is of a different nature being based on the regularity obtained by an Aronson–Bénilan type estimate which is related to the method in [14]. Our approach also provides two notable extensions, the cross-reaction terms and general initial data encompassing both overlap and vacuum.

**Fig. 1.** Comparison of evolution in time of solutions to system (1) (blue and red line) and the corresponding pressure (green line) for different values of  $\gamma$ :  $\gamma = 5$  (upper panels) and  $\gamma = 40$  (lower panels) (color figure online)

**Fig. 2.** Solutions to (1) and corresponding pressure in the presence of vacuum. The system is initialised with two indicator functions with supports at a positive distance. The densities remain segregated, in agreement with known results on segregated solutions (see, e.g., [9])

An Aronson–Bénilan type estimate seems necessary. In the one species case it provides uniform  $L^1$  estimates on  $\Delta p_\gamma$  which are needed to establish the complementarity relation. They face two issues in the present context. Firstly, the correct quantity has to be manipulated since  $\Delta p_\gamma$  is not enough, and the need to find the appropriate functional is standard, see [21]. Secondly, these estimates using an upper bound by the comparison principle are not adapted to systems and here we merely work in  $L^1$  for the positive part of the appropriate functional. Additionally, they provide estimates useful in the absence of good regularity for the population fractions  $c_\gamma^{(i)} := n_\gamma^{(i)}/n_\gamma$ , which come up naturally when writing the equation satisfied by the total population:

$$\frac{\partial n_\gamma}{\partial t} = \frac{\partial}{\partial x} \left( n_\gamma \frac{\partial p_\gamma}{\partial x} \right) + n_\gamma c_\gamma^{(1)} F(p_\gamma) + n_\gamma c_\gamma^{(2)} G(p_\gamma),$$

where we used the short-hand notation

$$F := F_1 + F_2, \quad \text{and} \quad G := G_1 + G_2.$$

The equation for the pressure also involves the fractions and reads as

$$\frac{\partial p_\gamma}{\partial t} = \left| \frac{\partial p_\gamma}{\partial x} \right|^2 + \gamma p_\gamma \left[ \frac{\partial^2 p_\gamma}{\partial x^2} + R \right], \quad R := c_\gamma^{(1)} F(p_\gamma) + c_\gamma^{(2)} G(p_\gamma).$$

Even for a fixed  $\gamma$ , the population fractions are ambiguously defined whenever  $n_\gamma = 0$ , a scenario that typically occurs in segregation. We shall see that the population fractions do not have a well-posed limit equation, at least with the available regularity results.

We also emphasise that this problem adds up to the more classical difficulties arising from the system structure, namely that comparison principles are not available since the interaction is neither competitive nor cooperative.

**Main results.** Our aim is to prove convergence for  $n_\gamma^{(1)}$ ,  $n_\gamma^{(2)}$ ,  $n_\gamma$  and  $p_\gamma$  on  $\mathbb{R} \times (0, T)$ , for all  $T > 0$ , and to state the limit equations which extend (4)–(5) to two species.

As is usual for these equations of porous medium type, the solution to (1) remains compactly supported for all times whenever the initial data are (which we will assume throughout); see [33].

Then, the standard idea to deal with the lack of regularity coming from  $c_\gamma^{(1)}$ ,  $c_\gamma^{(2)}$  and the free boundary, is to shift the initial data as follows:

$$n_{0,\varepsilon}^{(i)}(x) = n_0^{(i)}(x) + \varepsilon.$$

After such a regularisation, we prove that the density  $n_{\gamma,\varepsilon}$  can no longer vanish, which implies that the quotients  $c_{\gamma,\varepsilon}^{(1)}$  and  $c_{\gamma,\varepsilon}^{(2)}$  are well defined. Furthermore, the equation for  $n_{\gamma,\varepsilon}$  (at the  $\varepsilon$  level) is satisfied in the strong sense. We also recover the classical feature that uniform upper bounds hold for both densities and for the pressure.

Building on this, we are in the position to prove several *a priori* estimates required to obtain enough compactness to pass to the incompressible limit and prove the complementarity relation. The key estimate is concerned with  $\frac{\partial^2 p_\gamma}{\partial x^2}$ , as it happens to be crucial in order to get compactness for  $\frac{\partial p_\gamma}{\partial x}$ . For this, we will adapt an argument introduced for the porous medium equation by ARONSON and BÉNILAN [1].

The next step is to pass to the limit  $\varepsilon \rightarrow 0, \gamma \rightarrow +\infty$  to obtain the complementarity relation and the limit equations; in doing this, we do not obtain equations for the  $c_\infty^{(i)}$ , but we make sure that the defining relations  $c_{\gamma,\varepsilon}^{(i)} n_{\gamma,\varepsilon} = n_{\gamma,\varepsilon}^{(i)}$  remain true at the limit on  $\{n_\infty > 0\}$ . The resulting theorem is our main result and is stated informally below.

**Theorem 1.1.** (Complementarity relation) *With the assumptions of Section 2.1, we may pass to the limit in Eq. (16) to obtain the complementarity relation*

$$p_\infty \left[ \frac{\partial^2 p_\infty}{\partial x^2} + n_\infty^{(1)} F(p_\infty) + n_\infty^{(2)} G(p_\infty) \right] = 0. \tag{6}$$

Here  $n_\infty^{(i)}, i = 1, 2$  and  $p_\infty$  weakly satisfy the equations, with  $n_\infty = n_\infty^{(1)} + n_\infty^{(2)}$ ,

$$\begin{cases} \frac{\partial n_\infty^{(1)}}{\partial t} = \frac{\partial}{\partial x} \left( n_\infty^{(1)} \frac{\partial p_\infty}{\partial x} \right) + n_\infty^{(1)} F_1(p_\infty) + n_\infty^{(2)} G_1(p_\infty), \\ \frac{\partial n_\infty^{(2)}}{\partial t} = \frac{\partial}{\partial x} \left( n_\infty^{(2)} \frac{\partial p_\infty}{\partial x} \right) + n_\infty^{(1)} F_2(p_\infty) + n_\infty^{(2)} G_2(p_\infty), \\ 0 = p_\infty(1 - n_\infty). \end{cases} \tag{7}$$

Note that the limit equations are written without using the population fractions,  $c_\infty^{(i)}$ , due to the relations

$$c_\infty^{(i)} n_\infty = n_\infty^{(i)}, \quad \text{and} \quad c_\infty^{(i)} p_\infty = n_\infty^{(i)} p_\infty,$$

for  $i = 1, 2$ .

We also establish that segregation is preserved at the limit in the absence of cross-reactions: if initially  $n_\infty^{(1)} n_\infty^{(2)} = 0$ , it remains true for all further times. Finally, and although we do not use them here, we derive some energy estimates which are gathered in ‘‘Appendix A’’ for the sake of completeness.

Note that the equality in (6) holds both in the distributional sense and, for a.e.  $t > 0$ , pointwise in  $x$  because we establish that  $p_\infty$  is continuous in space and  $\frac{\partial^2 p_\infty}{\partial x^2}$  is a bounded measure.

**Outline of the paper.** The rest of this paper is organised as follows: in Section 2 we first set up the problem and state the assumptions on the reaction terms as well as the initial data, and explain why we are handling compactly supported solutions. We then introduce the regularisation by  $\varepsilon$  and prove that the total density is bounded away from 0. Section 3 is devoted to deriving all *a priori* estimates necessary for compactness. Section 4 is dedicated to the incompressible limit, culminating in Theorem 1.1. We then tackle the problem of segregation in Section 5, and conclude the paper with Section 6, reiterating the strategy we have employed and its limitation raising several open questions.

## 2. Preliminaries and Regularisation

We introduce the assumptions we need in the study of system (1)–(3) when  $\gamma$  tends to  $\infty$ .

### 2.1. Assumptions and Initial Data

**Definition 2.1.** (*Feasible data*) We say that the growth functions  $F_i, G_i, i = 1, 2$  are feasible if they satisfy

- (i)  $F_i, G_i \in C_b^1(\mathbb{R}_+, \mathbb{R}), i = 1, 2,$
- (ii) for any  $p \geq 0$  there holds

$$F'_1(p), G'_2(p) < 0, \quad \text{as well as} \quad F'_2(p), G'_1(p) \leq 0,$$

- (iii) there exists  $P_H > 0$  such that for all  $p \geq P_H$ :

$$F_1(p), G_2(p) \leq 0, \quad \text{as well as} \quad F_2(p), G_1(p) = 0,$$

- (iv) there holds

$$F(0) = G(0).$$

Throughout the paper we refer to  $P_H$  as the **homeostatic pressure**.

In the definition above,  $C_b^1(\mathbb{R}_+, \mathbb{R})$  is the space of  $C^1(\mathbb{R}_+, \mathbb{R})$  functions with bounded derivatives.

The last equality is technical but instrumental for the Aronson–Bénilan estimates, as in [14][Theorem 2] about the stability of weak solutions with respect to the initial data, even though it is not used in the existence result of [9].

We now gather the assumptions made on the initial data. First, we assume that the initial conditions are compactly supported in some  $\Omega_0$  independent of  $\gamma$ , namely

$$\text{supp} \left( n_{\gamma, \text{init}}^{(i)} \right) \subset \Omega_0. \tag{8}$$

We define the regularised initial data for  $\varepsilon > 0$  as

$$n_{\gamma, \varepsilon, \text{init}}^{(i)} = n_{\gamma, \text{init}}^{(i)} + \varepsilon \quad \text{on } \mathbb{R}, \quad i = 1, 2,$$

and we make the following set of assumptions regarding how the initial data and  $\gamma, \varepsilon$  are related:

**Definition 2.2.** (*Well-prepared initial data*) We say the initial data are well prepared if there exist  $n_{\infty, \text{init}}^{(1)}, n_{\infty, \text{init}}^{(2)}$  in  $L^1(\Omega_0), \varepsilon_0 > 0$  and  $C > 0$  independent of both  $\gamma > 1$  and  $\varepsilon \leq \varepsilon_0$ , such that for  $i = 1, 2$ , and all  $\gamma > 1, \varepsilon \leq \varepsilon_0$  there holds

$$p_{\gamma, \varepsilon}(0) \leq P_H, \quad \lim_{\gamma \rightarrow +\infty} \left\| n_{\gamma, \text{init}}^{(i)} - n_{\infty, \text{init}}^{(i)} \right\|_{L^1(\Omega_0)} = 0, \quad \left\| \frac{\partial n_{\gamma, \text{init}}^{(i)}}{\partial x} \right\|_{L^1(\Omega_0)} \leq C, \tag{9}$$

$$\left\| \frac{\partial^2 p_{\gamma,\varepsilon}}{\partial x^2}(0) \right\|_{L^1(\Omega_0)} \leq C, \tag{10}$$

$$\left\| \frac{n_{\gamma,\varepsilon,\text{init}}^{(i)}}{n_{\gamma,\varepsilon,\text{init}}^{(1)} + n_{\gamma,\varepsilon,\text{init}}^{(2)}} \right\|_{\text{BV}(\Omega_0)} \leq C. \tag{11}$$

The first set of conditions (9) is standard and allows us to recover a density at time 0 when passing to the incompressible limit. The second condition (10) is technical and will be required when deriving some *a priori* estimates in Section 4. The last set of conditions (11) appears rather technical at first glance, but it is a natural assumption, cf. also [9], as it allows us to handle the points where both initial densities vanish, i.e., vacuum or the absence of any species.

Assuming feasible data, well-prepared and compactly supported initial conditions (8), we know from [14][Theorem 3], that system (1) admits a global weak solution  $n_\gamma^{(1)}, n_\gamma^{(2)}, p \in L^\infty(\mathbb{R} \times (0, T))$ , for all  $T > 0$ . More precisely, the pressure is shown to satisfy

$$\frac{\partial p_\gamma}{\partial x} \in L^2(\mathbb{R} \times (0, T)), \quad \frac{\partial^2 p_\gamma}{\partial x^2} \in L^\infty(0, T; L^1(\mathbb{R})),$$

and the weak solutions are to be understood in the following sense: for all  $\phi \in C^1_{\text{comp}}(\mathbb{R} \times (0, T))$ ,  $i = 1, 2$

$$\begin{aligned} & \int_0^T \int_{\mathbb{R}} \left[ -n_\gamma^{(i)} \frac{\partial \phi}{\partial t} + n_\gamma^{(i)} \frac{\partial p_\gamma}{\partial x} \frac{\partial \phi}{\partial x} - \left( n_\gamma^{(1)} F_i(p_\gamma) + n_\gamma^{(2)} G_i(p_\gamma) \right) \phi \right] dx dt \\ & = \int_{\mathbb{R}} n_{\gamma,\text{init}}^{(i)} \phi(0) dx. \end{aligned} \tag{12}$$

### 2.2. Compact Support

Let us start by a few remarks on notation. Throughout, we write

$$|x|_+ := \begin{cases} x, & x > 0, \\ 0, & x \leq 0, \end{cases} \quad \text{as well as} \quad |x|_- := \begin{cases} -x, & x < 0, \\ 0, & x \geq 0, \end{cases}$$

in order to denote the positive part of  $x \in \mathbb{R}$  and the negative part of  $x$ , respectively. In particular note that then  $x = |x|_+ - |x|_-$  and  $|x| = |x|_+ + |x|_-$ . In the same fashion we define the positive sign and negative sign

$$\text{sign}_+(x) := \begin{cases} 1, & x > 0, \\ 0, & x \leq 0, \end{cases} \quad \text{as well as} \quad \text{sign}_-(x) := \begin{cases} -1, & x < 0, \\ 0, & x \geq 0. \end{cases} \tag{13}$$

Note in particular that  $x \cdot \text{sign}_\pm(x) = |x|_\pm$ .

**Remark 1.** Throughout the paper, we shall obtain estimates for  $|\cdot|_\pm$  and  $|\cdot|$  by multiplying by functions of the type of (13). This is a standard approach for such types of equations [29], and can be rigorously justified as in [6].

Before regularising, we prove that solutions are compactly supported for all times, a result which requires checking that our assumptions ensure that both densities remain nonnegative.

**Proposition 1.** (Nonnegativity of  $n_\gamma^{(1)}$  and  $n_\gamma^{(2)}$ ) *There holds, for all  $t \geq 0$ , that*

$$n_\gamma^{(1)}(t, x) \geq 0 \quad \text{and} \quad n_\gamma^{(2)}(t, x) \geq 0.$$

**Proof.** Dealing with a model as the porous medium equation [33], we can multiply the first equation in (1) by  $\text{sign}_- \left( n_\gamma^{(1)} \right)$ , to obtain

$$\frac{\partial}{\partial t} \left| n_\gamma^{(1)} \right|_- - \frac{\partial}{\partial x} \left( \left| n_\gamma^{(1)} \right|_- \frac{\partial p_\gamma}{\partial x} \right) = \left| n_\gamma^{(1)} \right|_- F_1(p_\gamma) + n_\gamma^{(2)} G_1(p_\gamma) \text{sign}_- \left( n_\gamma^{(1)} \right),$$

by Remark 1. Observe now that

$$n_\gamma^{(2)} G_1(p_\gamma) \text{sign}_- \left( n_\gamma^{(1)} \right) = \left( \left| n_\gamma^{(2)} \right|_+ - \left| n_\gamma^{(2)} \right|_- \right) G_1(p_\gamma) \text{sign}_- \left( n_\gamma^{(1)} \right).$$

Since  $G_1(\cdot) \geq 0$ , by Definition 2.1 we may write

$$\begin{aligned} n_\gamma^{(2)} G_1(p_\gamma) \text{sign}_- \left( n_\gamma^{(1)} \right) &\leq -\text{sign}_- \left( n_\gamma^{(1)} \right) \left| n_\gamma^{(2)} \right|_- G_1(p_\gamma) \\ &\leq G_1(0) \left| n_\gamma^{(2)} \right|_-, \end{aligned}$$

where the last line is due to the fact that  $G_1$  is decreasing in its argument, by Definition 2.1. Thus, we may conclude

$$\frac{\partial}{\partial t} \left| n_\gamma^{(1)} \right|_- - \frac{\partial}{\partial x} \left( \left| n_\gamma^{(1)} \right|_- \frac{\partial p_\gamma}{\partial x} \right) \leq \left| n_\gamma^{(1)} \right|_- F_1(p_\gamma) + G_1(0) \left| n_\gamma^{(2)} \right|_-.$$

A similar computation for the second species yields

$$\frac{\partial}{\partial t} \left| n_\gamma^{(2)} \right|_- - \frac{\partial}{\partial x} \left( \left| n_\gamma^{(2)} \right|_- \frac{\partial p_\gamma}{\partial x} \right) \leq F_2(0) \left| n_\gamma^{(1)} \right|_- + G_2(p_\gamma) \left| n_\gamma^{(2)} \right|_-,$$

whence, upon adding both and integrating the sum in space, we obtain

$$\frac{d}{dt} \int_{\mathbb{R}} \left( \left| n_\gamma^{(1)} \right|_- + \left| n_\gamma^{(2)} \right|_- \right) dx \leq C \int_{\mathbb{R}} \left( \left| n_\gamma^{(1)} \right|_- + \left| n_\gamma^{(2)} \right|_- \right) dx,$$

where  $C$  only depends on the  $L^\infty$ -bounds of  $F_i, G_i, i = 1, 2$ . Applying Gronwall’s lemma gives

$$\int_{\mathbb{R}} \left( \left| n_\gamma^{(1)} \right|_- + \left| n_\gamma^{(2)} \right|_- \right) dx \leq 0,$$

and, thus,  $n_\gamma^{(1)}(t, x) \geq 0$  and  $n_\gamma^{(2)}(t, x) \geq 0$  for all  $t \geq 0$ .  $\square$

We can now prove that solutions of (1) are compactly supported for all times.

**Proposition 2.** *For all  $T > 0$ , there exists an open set  $\Omega$  independent of  $\gamma$  such that,*

$$\text{supp}(p_\gamma(t)) \subset \Omega, \quad \forall t \in [0, T].$$

**Proof.** We note that we may write the pressure equation as

$$\frac{\partial p_\gamma}{\partial t} = \left| \frac{\partial p_\gamma}{\partial x} \right|^2 + \gamma p_\gamma \frac{\partial^2 p_\gamma}{\partial x^2} + \gamma n_\gamma^{\gamma-1} \left( n_\gamma^{(1)} F(p_\gamma) + n_\gamma^{(2)} G(p_\gamma) \right),$$

and at this stage we do not need to use the fractions  $c_\gamma^{(1)}, c_\gamma^{(2)}$ . Since  $n_\gamma^{(1)}, n_\gamma^{(2)} \geq 0$ , we have  $n_\gamma^{(1)} F(p_\gamma) + n_\gamma^{(2)} G(p_\gamma) \leq (n_\gamma^{(1)} + n_\gamma^{(2)}) \max(F(p_\gamma), G(p_\gamma)) = n_\gamma \max(F(p_\gamma), G(p_\gamma))$ . We infer

$$\begin{aligned} \frac{\partial p_\gamma}{\partial t} &\leq \left| \frac{\partial p_\gamma}{\partial x} \right|^2 + \gamma p_\gamma \frac{\partial^2 p_\gamma}{\partial x^2} + \gamma n_\gamma^{\gamma-1} n_\gamma \max(F(p_\gamma), G(p_\gamma)) \\ &= \left| \frac{\partial p_\gamma}{\partial x} \right|^2 + \gamma p_\gamma \frac{\partial^2 p_\gamma}{\partial x^2} + \gamma p_\gamma \max(F(p_\gamma), G(p_\gamma)). \end{aligned}$$

Therefore  $p_\gamma$  is a subsolution of the equation satisfied with reaction function  $\max(F, G)$ . For this equation, it is well known that compactly supported initial data leads to a compactly supported solution for all times [29].  $\square$

We may without loss of generality assume that  $\Omega = (-L, L)$  for some  $L > 0$ , and we define the set  $Q_T := \Omega \times (0, T)$ . We fix these arbitrary parameters  $T$  and  $L$ .

### 2.3. Regularisation and Strong Solutions

As explained above, the regularisation step is purely technical, yet necessary, for the rigorous derivation of the *a priori* estimates in the subsequent section.

**Regularised equations.** We denote by  $n_{\gamma,\varepsilon}^{(1)}, n_{\gamma,\varepsilon}^{(2)}$  the solutions of the system when the initial data are the regularised ones:  $n_{\gamma,\varepsilon}^{(i)} = n_{\gamma,\text{init}}^{(i)} + \varepsilon, i = 1, 2$  for  $\varepsilon > 0$ . From now on, we consider the system

$$\begin{cases} \frac{\partial n_{\gamma,\varepsilon}^{(1)}}{\partial t} = \frac{\partial}{\partial x} \left( n_{\gamma,\varepsilon}^{(1)} \frac{\partial p_{\gamma,\varepsilon}}{\partial x} \right) + n_{\gamma,\varepsilon}^{(1)} F_1(p_{\gamma,\varepsilon}) + n_{\gamma,\varepsilon}^{(2)} G_1(p_{\gamma,\varepsilon}), \\ \frac{\partial n_{\gamma,\varepsilon}^{(2)}}{\partial t} = \frac{\partial}{\partial x} \left( n_{\gamma,\varepsilon}^{(2)} \frac{\partial p_{\gamma,\varepsilon}}{\partial x} \right) + n_{\gamma,\varepsilon}^{(1)} F_2(p_{\gamma,\varepsilon}) + n_{\gamma,\varepsilon}^{(2)} G_2(p_{\gamma,\varepsilon}), \end{cases} \quad (14)$$

with, as before,  $p_{\gamma,\varepsilon} = n_{\gamma,\varepsilon}^\gamma$  with  $n_{\gamma,\varepsilon} = n_{\gamma,\varepsilon}^{(1)} + n_{\gamma,\varepsilon}^{(2)}$ .

The regularised total density  $n_{\gamma,\varepsilon}$  satisfies the equation

$$\frac{\partial n_{\gamma,\varepsilon}}{\partial t} = \frac{\partial}{\partial x} \left( n_{\gamma,\varepsilon} \frac{\partial p_{\gamma,\varepsilon}}{\partial x} \right) + n_{\gamma,\varepsilon} c_{\gamma,\varepsilon}^{(1)} F(p_{\gamma,\varepsilon}) + n_{\gamma,\varepsilon} c_{\gamma,\varepsilon}^{(2)} G(p_{\gamma,\varepsilon}), \quad (15)$$

which we endow with homogeneous Neumann boundary conditions

$$\frac{\partial n_{\gamma,\varepsilon}}{\partial x}(t, x) = 0, \quad x = \pm L.$$

Thanks to [14][Theorem 2], as  $\varepsilon \rightarrow 0$ , solutions of the regularised system converge towards those of the original one. More precisely,  $n_{\gamma,\varepsilon}^{(i)}$  converges to  $n_\gamma^{(i)}$  in  $L^\infty(Q_T) - w*$  for  $i = 1, 2$ ,  $n_{\gamma,\varepsilon}, p_{\gamma,\varepsilon}$  converge to  $n_\gamma, p_\gamma$ , in  $L^q(Q_T)$ ,  $1 \leq q < \infty$ . Moreover,  $\partial_x p_{\gamma,\varepsilon}$  strongly converges to  $\partial_x p_\gamma$  in  $L^2(Q_T)$ .

As we shall now prove, the regularised total density is positive. This allows us to define the quotients  $c_{\gamma,\varepsilon}^{(1)}$  and  $c_{\gamma,\varepsilon}^{(2)}$ . On the other hand, the positivity ensures that  $n_{\gamma,\varepsilon}$  is a strong solution of (15). In fact, the regularisation allows us to get rid of the degenerate parabolicity of the equation, and then solutions are classical [33][Theorem 3.1].

Finally, the associated pressure satisfies, in the strong sense,

$$\frac{\partial p_{\gamma,\varepsilon}}{\partial t} = \left| \frac{\partial p_{\gamma,\varepsilon}}{\partial x} \right|^2 + \gamma p_{\gamma,\varepsilon} \left[ \frac{\partial^2 p_{\gamma,\varepsilon}}{\partial x^2} + R_{\gamma,\varepsilon} \right]. \tag{16}$$

From now on, we keep the regularisation parameter  $\varepsilon > 0$  in the statement of all propositions and theorems below while dropping it in the proofs to allow for an improved readability.

**Positivity for the density.** We now build a subsolution for the equation of  $n_{\gamma,\varepsilon}$ . A difficulty is that we cannot hope to derive any general comparison result at the level of the system. For that reason, the control from below relies on the observation that, thanks to the definition of  $p_\gamma$ , (15) can be rewritten in a porous medium equation form:

$$\frac{\partial n_{\gamma,\varepsilon}}{\partial t} - \frac{\gamma}{\gamma + 1} \frac{\partial^2}{\partial x^2} \left( n_{\gamma,\varepsilon}^{\gamma+1} \right) = n_{\gamma,\varepsilon} R_{\gamma,\varepsilon}. \tag{17}$$

**Proposition 3** (Positivity for the density  $n_{\gamma,\varepsilon}$ ). *The solution to (15) satisfies*

$$n_{\gamma,\varepsilon} \geq \underline{n}_\gamma := 2\varepsilon e^{-R_\infty t} > 0$$

for  $t \in (0, T]$ , where  $R_\infty > 0$  is a  $L^\infty$  bound for  $|R_{\gamma,\varepsilon}|$ .

**Proof.** We have chosen  $\underline{n}_\gamma$  so that  $\frac{\partial \underline{n}_\gamma}{\partial t} = -R_\infty \underline{n}_\gamma$  and  $\underline{n}_\gamma(0) = 2\varepsilon \leq n_\gamma(0)$ .

Subtracting the equations for  $\underline{n}_\gamma$  and  $n_\gamma$  we get

$$\frac{\partial}{\partial t} \left( \underline{n}_\gamma - n_\gamma \right) - \frac{\gamma}{\gamma + 1} \frac{\partial^2}{\partial x^2} \left( \underline{n}_\gamma^{\gamma+1} - n_\gamma^{\gamma+1} \right) = -R_\infty \underline{n}_\gamma - n_\gamma R.$$

Multiplying by  $\text{sign}_+(\underline{n}_\gamma - n_\gamma)$  and using that  $\text{sign}_+(\underline{n}_\gamma^{\gamma+1} - n_\gamma^{\gamma+1}) = \text{sign}_+(\underline{n}_\gamma - n_\gamma)$ , we arrive at

$$\begin{aligned} & \frac{\partial}{\partial t} \left| \underline{n}_\gamma - n_\gamma \right|_+ - \frac{\gamma}{\gamma + 1} \frac{\partial^2}{\partial x^2} \left| \underline{n}_\gamma^{\gamma+1} - n_\gamma^{\gamma+1} \right|_+ \\ & \leq \left( -R_\infty \underline{n}_\gamma - n_\gamma R \right) \text{sign}_+(\underline{n}_\gamma - n_\gamma). \end{aligned}$$

We now observe that we can write

$$-R_\infty \underline{n}_\gamma - n_\gamma R = \underline{n}_\gamma (-R_\infty - R) + R (\underline{n}_\gamma - n_\gamma).$$

Using that the quantity  $-R_\infty - R$  is always negative thanks to the definition of  $R_\infty$ , we obtain

$$\frac{\partial}{\partial t} \left| \underline{n}_\gamma - n_\gamma \right|_+ - \frac{\gamma}{\gamma + 1} \frac{\partial^2}{\partial x^2} \left| \underline{n}_\gamma^{\gamma+1} - n_\gamma^{\gamma+1} \right|_+ \leq R \left| \underline{n}_\gamma - n_\gamma \right|_+.$$

Integrating in space yields

$$\frac{d}{dt} \int_\Omega \left| \underline{n}_\gamma - n_\gamma \right|_+ dx \leq R_\infty \int_\Omega \left| \underline{n}_\gamma - n_\gamma \right|_+ dx,$$

which, thanks to Gronwall’s lemma and the hypothesis on initial conditions, implies that a.e.  $n_\gamma(t, x) \geq \underline{n}_\gamma(t, x)$  for  $t \in (0, T]$ .  $\square$

**Remark 2.** More generally, the previous result shows that for every nonnegative  $\underline{n}_\gamma$  and  $\bar{n}_\gamma$  that satisfy, respectively,

$$\begin{aligned} \frac{\partial \underline{n}_\gamma}{\partial t} - \frac{\gamma}{\gamma + 1} \frac{\partial^2 \underline{n}_\gamma^{\gamma+1}}{\partial x^2} &\leq -R_\infty \underline{n}_\gamma, \\ \frac{\partial \bar{n}_\gamma}{\partial t} - \frac{\gamma}{\gamma + 1} \frac{\partial^2 \bar{n}_\gamma^{\gamma+1}}{\partial x^2} &\geq R_\infty \bar{n}_\gamma, \end{aligned}$$

with  $R_\infty > 0$  as in Proposition 3, we have a.e. in  $Q_T$  that

$$\underline{n}_\gamma(t, x) \leq n_\gamma(t, x) \leq \bar{n}_\gamma(t, x).$$

**Proposition 4.** (Uniform bounds for  $n_{\gamma,\varepsilon}$  and  $p_{\gamma,\varepsilon}$ ) *The solution of (15), satisfies for a.e.  $(t, x) \in Q_T$*

$$0 < n_{\gamma,\varepsilon}(t, x) \leq P_H^{1/\gamma} \quad \text{and} \quad 0 < p_{\gamma,\varepsilon}(t, x) \leq P_H.$$

**Proof.** From Proposition 3, it is clear that  $p_\gamma = (n_\gamma)^\gamma > 0$ .

As for the  $L^\infty$  bounds, we set  $n_H = (P_H)^{1/\gamma}$  and observe that, for every  $0 \leq \zeta, \xi \leq 1$ ,

$$0 \geq n_H (\zeta F(P_H) + \xi G(P_H)),$$

thanks to the definition of  $P_H$ . Thus, we can choose  $\zeta = c_\gamma^{(1)}$  and  $\xi = c_\gamma^{(2)}$  and say that

$$\begin{aligned} &\frac{\partial}{\partial t} (n_\gamma - n_H) - \frac{\gamma}{\gamma + 1} \frac{\partial^2}{\partial x^2} (n_\gamma^{\gamma+1} - n_H^{\gamma+1}) \\ &= R (n_\gamma - n_H) + n_H \left[ c_\gamma^{(1)} (F(p) - F(P_H)) + c_\gamma^{(2)} (G(p) - G(P_H)) \right]. \end{aligned}$$

Multiplying by  $\text{sign}_+(n_\gamma - n_H)$  and observing that

$$(F(p_\gamma) - F(P_H)) \text{sign}_+(n_\gamma - n_H), (G(p_\gamma) - G(P_H)) \text{sign}_+(n_\gamma - n_H) \leq 0,$$

thanks to Definition 2.1, we get

$$\frac{\partial}{\partial t} |n_\gamma - n_H|_+ - \frac{\gamma}{\gamma + 1} \frac{\partial^2}{\partial x^2} |n_\gamma^{\gamma+1} - n_H^{\gamma+1}|_+ \leq R |n_\gamma - n_H|_+.$$

Integrating in space and using Gronwall’s lemma, we obtain

$$\frac{d}{dt} \int_\Omega |n_\gamma - n_H|_+ dx \leq C \int_\Omega |n_\gamma - n_H|_+ dx,$$

which implies  $n_\gamma(t, x) \leq n_H$  and  $p_\gamma(t, x) \leq P_H$  for every  $t \in (0, T]$  since it holds initially by (9).  $\square$

### 2.4. Equations for the Fractions

Let us examine the equations satisfied by the concentrations  $0 \leq c_{\gamma,\varepsilon}^{(i)} = n_{\gamma,\varepsilon}^{(i)}/n_{\gamma,\varepsilon} \leq 1$  for  $i = 1, 2$ . Thanks to the positivity of  $n_{\gamma,\varepsilon}$  these quantities are well defined. In order to derive the equations satisfied by  $c_{\gamma,\varepsilon}^{(i)}$ ,  $i = 1, 2$ , we use the smoothness of  $n_{\gamma,\varepsilon}$ .

By (1) and (15), they formally satisfy

$$\begin{aligned} \frac{\partial c_{\gamma,\varepsilon}^{(1)}}{\partial t} &= \frac{1}{n_{\gamma,\varepsilon}} \left( \frac{\partial n_{\gamma,\varepsilon}^{(1)}}{\partial t} - \frac{n_{\gamma,\varepsilon}^{(1)}}{n_{\gamma,\varepsilon}} \frac{\partial n_{\gamma,\varepsilon}}{\partial t} \right) \\ &= \frac{1}{n_{\gamma,\varepsilon}} \frac{\partial}{\partial x} \left( n_{\gamma,\varepsilon}^{(1)} \frac{\partial p_{\gamma,\varepsilon}}{\partial x} \right) + c_{\gamma,\varepsilon}^{(1)} F_1(p_{\gamma,\varepsilon}) + c_{\gamma,\varepsilon}^{(2)} G_1(p_{\gamma,\varepsilon}) \\ &\quad - \frac{c_{\gamma,\varepsilon}^{(1)}}{n_{\gamma,\varepsilon}} \frac{\partial}{\partial x} \left( n_{\gamma,\varepsilon} \frac{\partial p_{\gamma,\varepsilon}}{\partial x} \right) - \left( c_{\gamma,\varepsilon}^{(1)} \right)^2 F(p_{\gamma,\varepsilon}) - c_{\gamma,\varepsilon}^{(1)} c_{\gamma,\varepsilon}^{(2)} G(p_{\gamma,\varepsilon}). \end{aligned}$$

Thus, observing that

$$\frac{1}{n_{\gamma,\varepsilon}} \frac{\partial}{\partial x} \left( n_{\gamma,\varepsilon}^{(1)} \frac{\partial p_{\gamma,\varepsilon}}{\partial x} \right) - \frac{c_{\gamma,\varepsilon}^{(1)}}{n_{\gamma,\varepsilon}} \frac{\partial}{\partial x} \left( n_{\gamma,\varepsilon} \frac{\partial p_{\gamma,\varepsilon}}{\partial x} \right) = \frac{\partial c_{\gamma,\varepsilon}^{(1)}}{\partial x} \frac{\partial p_{\gamma,\varepsilon}}{\partial x},$$

we derive the two equations for  $c_{\gamma,\varepsilon}^{(1)}$  and  $c_{\gamma,\varepsilon}^{(2)}$ :

$$\begin{aligned} \frac{\partial c_{\gamma,\varepsilon}^{(1)}}{\partial t} &= \frac{\partial c_{\gamma,\varepsilon}^{(1)}}{\partial x} \frac{\partial p_{\gamma,\varepsilon}}{\partial x} + c_{\gamma,\varepsilon}^{(1)} F_1(p_{\gamma,\varepsilon}) + c_{\gamma,\varepsilon}^{(2)} G_1(p_{\gamma,\varepsilon}) \\ &\quad - \left( c_{\gamma,\varepsilon}^{(1)} \right)^2 F(p_{\gamma,\varepsilon}) - c_{\gamma,\varepsilon}^{(1)} c_{\gamma,\varepsilon}^{(2)} G(p_{\gamma,\varepsilon}), \end{aligned} \tag{18}$$

$$\begin{aligned} \frac{\partial c_{\gamma,\varepsilon}^{(2)}}{\partial t} &= \frac{\partial c_{\gamma,\varepsilon}^{(2)}}{\partial x} \frac{\partial p_{\gamma,\varepsilon}}{\partial x} + c_{\gamma,\varepsilon}^{(1)} F_2(p_{\gamma,\varepsilon}) + c_{\gamma,\varepsilon}^{(2)} G_2(p_{\gamma,\varepsilon}) \\ &\quad - \left( c_{\gamma,\varepsilon}^{(2)} \right)^2 G(p_{\gamma,\varepsilon}) - c_{\gamma,\varepsilon}^{(1)} c_{\gamma,\varepsilon}^{(2)} F(p_{\gamma,\varepsilon}). \end{aligned} \tag{19}$$

Note that these equations are to be understood in the weak sense. For  $c_{\gamma,\varepsilon}^{(1)}$ , for example, it is given by

$$\begin{aligned} & \int_0^T \int_{\Omega} \left[ -c_{\gamma,\varepsilon}^{(1)} \frac{\partial \phi}{\partial t} + c_{\gamma,\varepsilon}^{(1)} \frac{\partial p_{\gamma,\varepsilon}}{\partial x} \frac{\partial \phi}{\partial x} + c_{\gamma,\varepsilon}^{(1)} \frac{\partial^2 p_{\gamma,\varepsilon}}{\partial x^2} \phi \right. \\ & \quad \left. - \left( c_{\gamma,\varepsilon}^{(1)} F_1(p_{\gamma,\varepsilon}) + c_{\gamma,\varepsilon}^{(2)} G_1(p_{\gamma,\varepsilon}) - \left( c_{\gamma,\varepsilon}^{(1)} \right)^2 F(p_{\gamma,\varepsilon}) - c_{\gamma,\varepsilon}^{(1)} c_{\gamma,\varepsilon}^{(2)} G(p_{\gamma,\varepsilon}) \right) \phi \right] dx dt \\ & = \int_{\Omega} c_{\gamma,\varepsilon}^{(1)}(0) \phi(0) dx. \end{aligned}$$

They are obtained by choosing  $\phi/n_{\gamma,\varepsilon}$  as a test function in the weak formulation (12) of the equations for  $n_{\gamma,\varepsilon}^{(1)}$  and  $n_{\gamma,\varepsilon}^{(2)}$ , with  $\phi$  smooth and compactly supported in  $\Omega$ . This choice of test function is made possible by the smoothness of  $n_{\gamma,\varepsilon}$ .

### 3. A Priori Estimates

Throughout,  $C$  will denote a constant independent of  $\gamma$  and  $\varepsilon$  (but which might depend on  $T$ ), which may also change from line to line. This section is dedicated to proving the following *a priori* estimates. The last estimate involves

$$w_{\gamma,\varepsilon} := \frac{\partial^2 p_{\gamma,\varepsilon}}{\partial x^2} + R_{\gamma,\varepsilon}. \tag{20}$$

**Theorem 3.1.** (A Priori Estimates)

$$\int_0^T \int_{\Omega} \left| \frac{\partial p_{\gamma,\varepsilon}}{\partial x} \right|^2 dx dt \leq C, \tag{21}$$

$$\sup_{0 \leq t \leq T} \int_{\Omega} \left( \left| \frac{\partial c_{\gamma,\varepsilon}^{(i)}}{\partial x} \right| + \left| \frac{\partial n_{\gamma,\varepsilon}^{(i)}}{\partial x} \right| \right) dx \leq C, \quad i = 1, 2, \tag{22}$$

$$\gamma \int_0^T \int_{\Omega} p_{\gamma,\varepsilon} |w_{\gamma,\varepsilon}| dx dt \leq C, \quad \sup_{0 \leq t \leq T} \int_{\Omega} |w_{\gamma,\varepsilon}|_- dx \leq C. \tag{23}$$

The proof of the theorem is split into several results that are proven below in chronological order. We remind the reader that the subscripts  $\varepsilon$  are dropped throughout the proof for ease of notation. As a matter of fact, the bounds are independent of  $\varepsilon$ .

**Proof.** (Estimate (21)). We integrate the equation for the pressure, Eq. (16), in space to obtain

$$\frac{d}{dt} \int_{\Omega} p_{\gamma} dx - \int_{\Omega} \left( \left| \frac{\partial p_{\gamma}}{\partial x} \right|^2 + \gamma p_{\gamma} \frac{\partial^2 p_{\gamma}}{\partial x^2} \right) dx = \gamma \int_{\Omega} p_{\gamma} R dx.$$

An integration by parts in the second-order term yields

$$\frac{d}{dt} \int_{\Omega} p_{\gamma} dx + (\gamma - 1) \int_{\Omega} \left| \frac{\partial p_{\gamma}}{\partial x} \right|^2 dx = \gamma \int_{\Omega} p_{\gamma} R dx,$$

having used the fact that  $p_\gamma \frac{\partial p_\gamma}{\partial x}$  vanishes at the boundary due to the Neumann boundary conditions. Finally, let us integrate in time to get

$$\begin{aligned}
 (\gamma - 1) \int_0^T \int_\Omega \left| \frac{\partial p_\gamma}{\partial x} \right|^2 dx dt &= \gamma \int_0^T \int_\Omega p_\gamma R dx dt \\
 - \|p_\gamma(T)\|_{L^1(\Omega)} + \|p_\gamma(0)\|_{L^1(\Omega)} &\leq C\gamma,
 \end{aligned}$$

as  $p_\gamma$  and  $R$  are bounded in  $L^\infty(Q_T)$  uniformly in  $\gamma$  and  $\varepsilon$ . We conclude by dividing by  $\gamma$  to obtain the desired estimate.  $\square$

**Proof.** (Estimate (22)). We begin by considering the equation for  $c_\gamma^{(1)}$  in Eq. (18). Upon differentiation in space, it holds that

$$\begin{aligned}
 \frac{\partial}{\partial t} \frac{\partial c_\gamma^{(1)}}{\partial x} &= \frac{\partial}{\partial x} \left( \frac{\partial c_\gamma^{(1)}}{\partial x} \frac{\partial p_\gamma}{\partial x} \right) + \frac{\partial c_\gamma^{(1)}}{\partial x} F_1(p_\gamma) + \frac{\partial c_\gamma^{(2)}}{\partial x} G_1(p_\gamma) \\
 &\quad - 2c_\gamma^{(1)} \frac{\partial c_\gamma^{(1)}}{\partial x} F(p_\gamma) - c_\gamma^{(2)} \frac{\partial c_\gamma^{(1)}}{\partial x} G(p_\gamma) - c_\gamma^{(1)} \frac{\partial c_\gamma^{(2)}}{\partial x} G(p_\gamma) \\
 &\quad + \frac{\partial p_\gamma}{\partial x} \left( c_\gamma^{(1)} F_1'(p_\gamma) + c_\gamma^{(2)} G_1'(p_\gamma) - (c_\gamma^{(1)})^2 F'(p_\gamma) - c_\gamma^{(1)} c_\gamma^{(2)} G'(p_\gamma) \right).
 \end{aligned}$$

Multiplying this equation by  $\text{sign}\left(\frac{\partial c_\gamma^{(1)}}{\partial x}\right)$  and using Remark 1, we obtain

$$\begin{aligned}
 \frac{\partial}{\partial t} \left| \frac{\partial c_\gamma^{(1)}}{\partial x} \right| &\leq \frac{\partial}{\partial x} \left( \left| \frac{\partial c_\gamma^{(1)}}{\partial x} \right| p_\gamma \right) + \left| \frac{\partial c_\gamma^{(1)}}{\partial x} \right| \left( F_1(p_\gamma) - 2c_\gamma^{(1)} F(p_\gamma) - c_\gamma^{(2)} G(p_\gamma) \right) \\
 &\quad + \frac{\partial c_\gamma^{(2)}}{\partial x} \left( G_1(p_\gamma) - c_\gamma^{(1)} G(p_\gamma) \right) \text{sign} \left( \frac{\partial c_\gamma^{(1)}}{\partial x} \right) \\
 &\quad + \frac{\partial p_\gamma}{\partial x} \left( c_\gamma^{(1)} F_1'(p_\gamma) + c_\gamma^{(2)} G_1'(p_\gamma) - (c_\gamma^{(1)})^2 F'(p_\gamma) \right. \\
 &\quad \left. - c_\gamma^{(1)} c_\gamma^{(2)} G'(p_\gamma) \right) \text{sign} \left( \frac{\partial c_\gamma^{(1)}}{\partial x} \right) \\
 &\leq \frac{\partial}{\partial x} \left( \left| \frac{\partial c_\gamma^{(1)}}{\partial x} \right| p_\gamma \right) + C \left| \frac{\partial c_\gamma^{(1)}}{\partial x} \right| + C \left| \frac{\partial c_\gamma^{(2)}}{\partial x} \right| + C \left| \frac{\partial p_\gamma}{\partial x} \right|,
 \end{aligned}$$

where the constants are independent of  $\gamma$  and  $\varepsilon$  and only depend on the  $L^\infty$ -bounds on  $F_i, G_i$ , as well as on the fact that  $0 \leq c_\gamma^{(i)} \leq 1, i = 1, 2$ . Upon integrating in space we get

$$\frac{d}{dt} \int_{\Omega} \left| \frac{\partial c_{\gamma}^{(1)}}{\partial x} \right| dx \leq C \int_{\Omega} \left( \left| \frac{\partial c_{\gamma}^{(1)}}{\partial x} \right| + \left| \frac{\partial c_{\gamma}^{(2)}}{\partial x} \right| \right) dx + C \int_{\Omega} \left| \frac{\partial p_{\gamma}}{\partial x} \right| dx,$$

where the first term has vanished as it was an exact derivative and the boundary terms vanish by the homogeneous Neumann boundary conditions.

Performing the same manipulations on the equation for  $c_{\gamma}^{(2)}$  and summing both, we finally get

$$\frac{d}{dt} \int_{\Omega} \left( \left| \frac{\partial c_{\gamma}^{(1)}}{\partial x} \right| + \left| \frac{\partial c_{\gamma}^{(2)}}{\partial x} \right| \right) dx \leq C \int_{\Omega} \left( \left| \frac{\partial c_{\gamma}^{(1)}}{\partial x} \right| + \left| \frac{\partial c_{\gamma}^{(2)}}{\partial x} \right| \right) dx + C \int_{\Omega} \left| \frac{\partial p_{\gamma}}{\partial x} \right| dx.$$

By setting

$$\psi(t) := \int_{\Omega} \left( \left| \frac{\partial c_{\gamma}^{(1)}}{\partial x} \right| + \left| \frac{\partial c_{\gamma}^{(2)}}{\partial x} \right| \right) dx,$$

the previous inequality reads as

$$\psi'(t) \leq C\psi(t) + C \int_{\Omega} \left| \frac{\partial p_{\gamma}}{\partial x} \right| dx.$$

An application of Gronwall’s lemma yields

$$\psi(t) \leq C\psi(0)e^{Ct} + C \int_0^t \int_{\Omega} e^{C(t-s)} \left| \frac{\partial p_{\gamma}}{\partial x} \right| dx ds.$$

From the uniform  $L^2(Q_T)$ -bounds on  $\frac{\partial p_{\gamma}}{\partial x}$ , we conclude that

$$\psi(t) \leq C\psi(0) + C.$$

At this stage let us emphasise that none of the constants depends on  $\gamma$  or  $\varepsilon$ . Finally, the term  $\psi(0)$  is bounded by the assumptions on the initial data, cf. Eq. (11).

For the densities  $n_{\gamma}^{(1)}, n_{\gamma}^{(2)}$ , we start by estimating the total density  $n_{\gamma}$ . We differentiate Eq. (15) w.r.t.  $x$ , which yields

$$\begin{aligned} \frac{\partial}{\partial t} \left( \frac{\partial n_{\gamma}}{\partial x} \right) &= \frac{\partial^2}{\partial x^2} \left( n_{\gamma} \frac{\partial p_{\gamma}}{\partial x} \right) + n_{\gamma} \left( \frac{\partial c_{\gamma}^{(1)}}{\partial x} F(p_{\gamma}) + \frac{\partial c_{\gamma}^{(2)}}{\partial x} G(p_{\gamma}) \right) \\ &\quad + \frac{\partial n_{\gamma}}{\partial x} \left( c_{\gamma}^{(1)} F(p_{\gamma}) \right. \\ &\quad \left. + c_{\gamma}^{(2)} G(p_{\gamma}) \right) + \frac{\partial p_{\gamma}}{\partial x} n_{\gamma} \left( c_{\gamma}^{(1)} F'(p_{\gamma}) + c_{\gamma}^{(2)} G'(p_{\gamma}) \right). \end{aligned}$$

Using  $n_{\gamma} \frac{\partial p_{\gamma}}{\partial x} = \gamma p_{\gamma} \frac{\partial n_{\gamma}}{\partial x}$  for the first term in the right-hand side, multiplying by  $\text{sign}(\frac{\partial n_{\gamma}}{\partial x}) = \text{sign}(\frac{\partial p_{\gamma}}{\partial x})$  and employing Remark 1, we obtain

$$\begin{aligned} \frac{\partial}{\partial t} \left| \frac{\partial n_\gamma}{\partial x} \right| &\leq \gamma \frac{\partial^2}{\partial x^2} \left( p_\gamma \left| \frac{\partial n_\gamma}{\partial x} \right| \right) + n_\gamma \left( \frac{\partial c_\gamma^{(1)}}{\partial x} F(p_\gamma) + \frac{\partial c_\gamma^{(2)}}{\partial x} G(p_\gamma) \right) \text{sign} \left( \frac{\partial n_\gamma}{\partial x} \right) \\ &\quad + \left| \frac{\partial n_\gamma}{\partial x} \right| \left( c_\gamma^{(1)} F(p_\gamma) + c_\gamma^{(2)} G(p_\gamma) \right) \\ &\quad + \left| \frac{\partial p_\gamma}{\partial x} \right| n_\gamma \left( c_\gamma^{(1)} F'(p_\gamma) + c_\gamma^{(2)} G'(p_\gamma) \right). \end{aligned}$$

Upon integrating in space and using the zero Neumann boundary conditions, we get

$$\frac{d}{dt} \int_\Omega \left| \frac{\partial n_\gamma}{\partial x} \right| dx \leq C \int_\Omega \left( \left| \frac{\partial c_\gamma^{(1)}}{\partial x} \right| + \left| \frac{\partial c_\gamma^{(2)}}{\partial x} \right| + \left| \frac{\partial n_\gamma}{\partial x} \right| + \left| \frac{\partial p_\gamma}{\partial x} \right| \right) dx,$$

where the constant  $C > 0$  only depends on the  $L^\infty$ -bounds of  $n_\gamma$ , as well as  $F_i, G_i$  and  $F'_i, G'_i$ , for  $i = 1, 2$ . Using the  $BV$ -bounds from above, we may further write

$$\frac{d}{dt} \int_\Omega \left| \frac{\partial n_\gamma}{\partial x} \right| dx \leq C + C \int_\Omega \left| \frac{\partial n_\gamma}{\partial x} \right| dx + \int_\Omega \left| \frac{\partial p_\gamma}{\partial x} \right| dx.$$

Proceeding as before, we conclude that  $n_\gamma$  is uniformly bounded in  $BV$ , cf. Definition 2.2, Eq. (11). To see that it provides the required  $BV$  estimates for  $n_\gamma^{(1)}, n_\gamma^{(2)}$ , we notice that the equality  $n_\gamma^{(i)} = c_\gamma^{(i)} n_\gamma$  leads to

$$\frac{\partial n_\gamma^{(i)}}{\partial x} = c_\gamma^{(i)} \frac{\partial n_\gamma}{\partial x} + n_\gamma \frac{\partial c_\gamma^{(i)}}{\partial x}$$

for  $i = 1, 2$ . The  $BV$  bounds for  $n_\gamma$  and  $c_\gamma^{(1)}$  and  $c_\gamma^{(2)}$  together with the boundedness of  $n_\gamma$  then imply the result and conclude the proof.  $\square$

**Proof.** (Estimate (23)). For ease on notations, we set  $R = c_\gamma^{(1)} F(p_\gamma) + c_\gamma^{(2)} G(p_\gamma)$ , as before, and we recall that  $R$  is bounded in  $L^\infty(Q_T)$ . Using Eqs. (16) and (18), we want to differentiate the quantity  $w_\gamma$  in time. We obtain

$$\frac{\partial w_\gamma}{\partial t} = \underbrace{\frac{\partial}{\partial t} \frac{\partial^2 p_\gamma}{\partial x^2}}_{I_1} + \underbrace{\frac{\partial R}{\partial t}}_{I_2}.$$

We shall address both terms individually beginning with  $I_2$ :

$$\begin{aligned} I_2 &= \frac{\partial}{\partial t} \left( c_\gamma^{(1)} F(p_\gamma) + c_\gamma^{(2)} G(p_\gamma) \right) \\ &= \underbrace{\frac{\partial c_\gamma^{(1)}}{\partial t} F(p_\gamma) + \frac{\partial c_\gamma^{(2)}}{\partial t} G(p_\gamma)}_{I_{2,1}} + \underbrace{\left( c_\gamma^{(1)} F'(p_\gamma) + c_\gamma^{(2)} G'(p_\gamma) \right) \frac{\partial p_\gamma}{\partial t}}_{I_{2,2}}. \end{aligned}$$

Using the equations for  $c_\gamma^{(i)}$ , Eq. (18), we obtain

$$\begin{aligned} I_{2,1} &= F(p_\gamma) \left( \frac{\partial c_\gamma^{(1)}}{\partial x} \frac{\partial p_\gamma}{\partial x} + c_\gamma^{(1)} F_1(p_\gamma) + c_\gamma^{(2)} G_1(p_\gamma) - \left( c_\gamma^{(1)} \right)^2 F(p_\gamma) \right. \\ &\quad \left. - c_\gamma^{(1)} c_\gamma^{(2)} G(p_\gamma) \right) \\ &\quad + G(p_\gamma) \left( \frac{\partial c_\gamma^{(2)}}{\partial x} \frac{\partial p_\gamma}{\partial x} + c_\gamma^{(1)} F_2(p_\gamma) + c_\gamma^{(2)} G_2(p_\gamma) \right. \\ &\quad \left. - \left( c_\gamma^{(2)} \right)^2 G(p_\gamma) - c_\gamma^{(1)} c_\gamma^{(2)} F(p_\gamma) \right) \\ &= \frac{\partial p_\gamma}{\partial x} \left( F(p_\gamma) \frac{\partial c_\gamma^{(1)}}{\partial x} + G(p_\gamma) \frac{\partial c_\gamma^{(2)}}{\partial x} \right) + S_2, \end{aligned}$$

where we introduced

$$\begin{aligned} S_2 &= F(p_\gamma) \left( c_\gamma^{(1)} F_1(p_\gamma) + c_\gamma^{(2)} G_1(p_\gamma) - \left( c_\gamma^{(1)} \right)^2 F(p_\gamma) - c_\gamma^{(1)} c_\gamma^{(2)} G(p_\gamma) \right) \\ &\quad + G(p_\gamma) \left( c_\gamma^{(1)} F_2(p_\gamma) + c_\gamma^{(2)} G_2(p_\gamma) - \left( c_\gamma^{(2)} \right)^2 G(p_\gamma) - c_\gamma^{(1)} c_\gamma^{(2)} F(p_\gamma) \right) \end{aligned} \tag{24}$$

as a shorthand. Similarly, we may use the equation for  $p_\gamma$  to obtain

$$I_{2,2} = \left( c_\gamma^{(1)} F'(p_\gamma) + c_\gamma^{(2)} G'(p_\gamma) \right) \gamma p_\gamma w_\gamma + S_1,$$

where

$$S_1 = \left( c_\gamma^{(1)} F'(p_\gamma) + c_\gamma^{(2)} G'(p_\gamma) \right) \left| \frac{\partial p_\gamma}{\partial x} \right|^2.$$

Now, recall that  $I_2 = I_{2,1} + I_{2,2}$ , so that

$$\begin{aligned} I_2 &= \gamma p_\gamma w_\gamma \left( c_\gamma^{(1)} F'(p_\gamma) + c_\gamma^{(2)} G'(p_\gamma) \right) \\ &\quad + \frac{\partial p_\gamma}{\partial x} \left( \frac{\partial c_\gamma^{(1)}}{\partial x} F(p_\gamma) + \frac{\partial c_\gamma^{(2)}}{\partial x} G(p_\gamma) \right) + S_1 + S_2. \end{aligned} \tag{25}$$

Recalling the pressure equation, Eq. (16), we obtain

$$\begin{aligned} I_1 &= \frac{\partial^2}{\partial x^2} \left( \left| \frac{\partial p_\gamma}{\partial x} \right|^2 + \gamma p_\gamma w_\gamma \right) \\ &= 2 \frac{\partial}{\partial x} \left( \frac{\partial p_\gamma}{\partial x} \frac{\partial^2 p_\gamma}{\partial x^2} \right) + \gamma \frac{\partial^2}{\partial x^2} (p_\gamma w_\gamma) \end{aligned}$$

$$\begin{aligned}
 &= 2 \frac{\partial}{\partial x} \left( \frac{\partial p_\gamma}{\partial x} w_\gamma - \frac{\partial p_\gamma}{\partial x} R \right) + \gamma \frac{\partial^2}{\partial x^2} (p_\gamma w_\gamma) \\
 &= 2 \frac{\partial}{\partial x} \left( \frac{\partial p_\gamma}{\partial x} w_\gamma \right) + \gamma \frac{\partial^2}{\partial x^2} (p_\gamma w_\gamma) - \underbrace{2 \frac{\partial}{\partial x} \left( \frac{\partial p_\gamma}{\partial x} R \right)}_{I_{1,1}}. \tag{26}
 \end{aligned}$$

Let us note that

$$\begin{aligned}
 I_{1,1} &= \frac{\partial}{\partial x} \left( \frac{\partial p_\gamma}{\partial x} R \right) \\
 &= \frac{\partial^2 p_\gamma}{\partial x^2} R + \frac{\partial p_\gamma}{\partial x} \left( \frac{\partial c_\gamma^{(1)}}{\partial x} F(p_\gamma) + \frac{\partial c_\gamma^{(2)}}{\partial x} G(p_\gamma) \right) + S_1 \\
 &= (w_\gamma - R)R + \frac{\partial p_\gamma}{\partial x} \left( \frac{\partial c_\gamma^{(1)}}{\partial x} F(p_\gamma) + \frac{\partial c_\gamma^{(2)}}{\partial x} G(p_\gamma) \right) + S_1,
 \end{aligned}$$

having used the fact that  $w_\gamma = \frac{\partial^2 p_\gamma}{\partial x^2} + R$ .

Combining the estimates on the pressure-related term, Eq. (26), with the reaction-related terms, Eq. (25), we obtain

$$\begin{aligned}
 \frac{\partial w_\gamma}{\partial t} &= \gamma \left[ \frac{\partial^2}{\partial x^2} (p_\gamma w_\gamma) + p_\gamma w_\gamma \left( c_\gamma^{(1)} F'(p_\gamma) + c_\gamma^{(2)} G'(p_\gamma) \right) \right] \\
 &\quad + 2 \frac{\partial}{\partial x} \left( \frac{\partial p_\gamma}{\partial x} w_\gamma \right) \\
 &\quad - 2(w_\gamma - R)R - \frac{\partial p_\gamma}{\partial x} \left( \frac{\partial c_\gamma^{(1)}}{\partial x} F(p_\gamma) + \frac{\partial c_\gamma^{(2)}}{\partial x} G(p_\gamma) \right) - S_1 + S_2. \tag{27}
 \end{aligned}$$

We now note that  $S_1 \leq 0$  since  $F$  and  $G$  are decreasing functions, cf. Definition 2.1. Moreover,  $|S_2| \leq C$ , since all the terms in Eq. (24) are uniformly bounded in  $\gamma$  and  $\varepsilon$ . Thus we may write  $S_2 \geq -|S_2| \geq -C$ , whence

$$\begin{aligned}
 \frac{\partial w_\gamma}{\partial t} &\geq \gamma \left[ \frac{\partial^2}{\partial x^2} (p_\gamma w_\gamma) + p_\gamma w_\gamma \left( c_\gamma^{(1)} F'(p_\gamma) + c_\gamma^{(2)} G'(p_\gamma) \right) \right] \\
 &\quad + 2 \frac{\partial}{\partial x} \left( \frac{\partial p_\gamma}{\partial x} w_\gamma \right) - 2w_\gamma R \\
 &\quad - \frac{\partial p_\gamma}{\partial x} \left( \frac{\partial c_\gamma^{(1)}}{\partial x} F(p_\gamma) + \frac{\partial c_\gamma^{(2)}}{\partial x} G(p_\gamma) \right) - C.
 \end{aligned}$$

Multiplying by  $\text{sign}_-(w_\gamma)$  yields

$$\begin{aligned}
 \frac{\partial}{\partial t} |w_\gamma|_- &\leq \gamma \left[ \frac{\partial^2}{\partial x^2} (p_\gamma |w_\gamma|_-) + p_\gamma |w_\gamma|_- \left( c_\gamma^{(1)} F'(p_\gamma) + c_\gamma^{(2)} G'(p_\gamma) \right) \right] \\
 &\quad + 2 \frac{\partial}{\partial x} \left( \frac{\partial p_\gamma}{\partial x} |w_\gamma|_- \right)
 \end{aligned}$$

$$-2 |w_\gamma|_- R + \frac{\partial p_\gamma}{\partial x} \left( \frac{\partial c_\gamma^{(1)}}{\partial x} F(p_\gamma) + \frac{\partial c_\gamma^{(2)}}{\partial x} G(p_\gamma) \right) \mathbb{1}_{\{w_\gamma \leq 0\}} + C,$$

where we used Remark 1. Using the  $L^\infty$ -bounds on the growth terms we estimate the right-hand side further:

$$\begin{aligned} \frac{\partial}{\partial t} |w_\gamma|_- &\leq \gamma \left[ \frac{\partial^2}{\partial x^2} (p_\gamma |w_\gamma|_-) + p_\gamma |w_\gamma|_- (c_\gamma^{(1)} F'(p_\gamma) + c_\gamma^{(2)} G'(p_\gamma)) \right] \\ &\quad + 2 \frac{\partial}{\partial x} \left( \frac{\partial p_\gamma}{\partial x} |w_\gamma|_- \right) + C |w_\gamma|_- + C \left| \frac{\partial p_\gamma}{\partial x} \right| \left( \left| \frac{\partial c_\gamma^{(1)}}{\partial x} \right| + \left| \frac{\partial c_\gamma^{(2)}}{\partial x} \right| \right) + C. \end{aligned} \tag{28}$$

Finally we note that

$$c_\gamma^{(1)} F'(p_\gamma) + c_\gamma^{(2)} G'(p_\gamma) \leq \max(F'(p_\gamma), G'(p_\gamma)) \leq -C < 0,$$

since  $c_\gamma^{(1)} + c_\gamma^{(2)} = 1$ , which is why Eq. (28) can be further estimated and we obtain

$$\begin{aligned} \frac{\partial}{\partial t} |w_\gamma|_- &\leq \gamma \left[ \frac{\partial^2}{\partial x^2} (p_\gamma |w_\gamma|_-) - C p_\gamma |w_\gamma|_- \right] \\ &\quad + 2 \frac{\partial}{\partial x} \left( \frac{\partial p_\gamma}{\partial x} |w_\gamma|_- \right) + C |w_\gamma|_- \\ &\quad + C \left| \frac{\partial p_\gamma}{\partial x} \right| \left( \left| \frac{\partial c_\gamma^{(1)}}{\partial x} \right| + \left| \frac{\partial c_\gamma^{(2)}}{\partial x} \right| \right) + C. \end{aligned}$$

Then, integrating in space yields

$$\begin{aligned} \frac{d}{dt} \int_\Omega |w_\gamma|_- \, dx &\leq -C\gamma \int_\Omega p_\gamma |w_\gamma|_- \, dx + C \int_\Omega |w_\gamma|_- \, dx \\ &\quad + C \left\| \frac{\partial p_\gamma}{\partial x} \right\|_{L^\infty(\Omega)} + C, \end{aligned} \tag{29}$$

where we used the  $BV$ -estimates on the  $c_\gamma^{(i)}$ 's (22). Next we show that the  $L^\infty$ -norm of  $\frac{\partial p_\gamma}{\partial x}$  can be estimated in terms of  $|w_\gamma|_-$ . First, due to Sobolev's embedding theorem in one dimension, we have

$$\begin{aligned} \left\| \frac{\partial p_\gamma}{\partial x} \right\|_{L^\infty(\Omega)} &\leq \left\| \frac{\partial^2 p_\gamma}{\partial x^2} \right\|_{L^1(\Omega)} \\ &\leq \int_\Omega (|w_\gamma| + |R|) \, dx \\ &= \int_\Omega (w_\gamma + 2|w_\gamma|_- + |R|) \, dx \\ &\leq \int_\Omega \left( \frac{\partial^2 p_\gamma}{\partial x^2} + 2|R| + 2|w_\gamma|_- \right) \, dx. \end{aligned}$$

Thus we have

$$\left\| \frac{\partial p_\gamma}{\partial x} \right\|_{L^\infty(\Omega)} \leq C + C \int_\Omega |w_\gamma|_- dx. \tag{30}$$

Using Eq. (30) in Eq. (29) we get

$$\frac{d}{dt} \int_\Omega |w_\gamma|_- dx \leq -C\gamma \int_\Omega |w_\gamma|_- dx + C \int_\Omega |w_\gamma|_- dx + C.$$

The above equation and the Gronwall lemma yield the first estimate of (23), provided that we can bound  $\|w_\gamma(0)\|_{L^1(\Omega)}$  independently of  $\gamma, \varepsilon$ , which in turn requires a  $L^1(\Omega)$  estimate for  $\frac{\partial^2 p_\gamma}{\partial x^2}(0)$ . Such an estimate is provided by (10).

Moreover, recalling (29), we also get

$$\gamma \int_0^T \int_\Omega p_\gamma |w_\gamma|_- dx \leq C. \tag{31}$$

From Eq. (16), we easily infer

$$\begin{aligned} \gamma \int_0^T \int_\Omega p_\gamma w_\gamma dx &= \int_0^T \int_\Omega \left( \frac{\partial p_\gamma}{\partial t} - \left| \frac{\partial p_\gamma}{\partial x} \right|^2 \right) dx \\ &\leq \|p_\gamma(T)\|_{L^1(\Omega)} - \|p_\gamma(0)\|_{L^1(\Omega)} \leq C. \end{aligned}$$

The above inequality, together with (31), completes the proof since it provides the required estimate for  $\gamma \int_0^T \int_\Omega p_\gamma |w_\gamma|_-$ .  $\square$

Among byproducts of the previous proof, we highlight the following estimates on  $\frac{\partial p_\gamma}{\partial x}, \frac{\partial^2 p_\gamma}{\partial x^2}$ , which will be useful for the proof of the main results:

**Corollary 1.** *There holds*

$$\left\| \frac{\partial p_{\gamma,\varepsilon}}{\partial x} \right\|_{L^\infty(\Omega)} \leq C, \quad \text{as well as} \quad \left\| \frac{\partial^2 p_{\gamma,\varepsilon}}{\partial x^2} \right\|_{L^1(\Omega)} \leq C.$$

### 4. Proof of the Main Results

This section is dedicated to passing to the incompressible limit  $\gamma \rightarrow +\infty$ . As before, we assume that the functions  $F_i, G_i$  are feasible, that the initial data is well-prepared and that the initial data is compactly supported, i.e., (8).

**Theorem 4.1.** (Strong compactness of the pressure) *Let  $1 \leq q < \infty$  be arbitrary. Then there exists a function  $p_\infty \in L^\infty(Q_T)$  such that, upon extraction of a sub-family, it holds that*

$$p_\gamma \longrightarrow p_\infty, \tag{32}$$

*pointwise and strongly in  $L^q(Q_T)$ .*

**Proof.** For a given sequence  $(u_\gamma)_\gamma$  defined on  $(0, T) \times \Omega$  and bounded in  $L^1(Q_T)$ , we recall that if we control both the time shifts and space shifts as follows:

$$\int_0^{T-h} \int_\Omega |u_\gamma(t+h, x+a) - u_\gamma(t, x)| \rightarrow 0, \tag{33}$$

as  $(h, a) \rightarrow (0, 0)$ , independently of  $\gamma$ , then  $(u_\gamma)_\gamma$  has compact closure in  $L^1(Q_T)$  by the Fréchet-Kolmogorov compactness theorem. This is of course true if the following stronger estimate holds:

$$\int_0^T \int_\Omega (|\partial_t u_\gamma| + |\partial_x u_\gamma|) \, dx dt \leq C. \tag{34}$$

Finally, if furthermore  $(u_\gamma)_\gamma$  is (uniformly in  $\gamma$ ) in  $L^\infty(Q_T)$ , then it is also compact in  $L^q(Q_T)$  for any  $1 \leq q < \infty$ , after applying Lebesgue’s dominated convergence theorem. This general result is crucial in passing to the limit  $\gamma \rightarrow +\infty$  and we will use it in this proof, abusively referring to it as the Fréchet-Kolmogorov theorem. From the estimates of Theorem 3.1, we clearly have that

$$\int_0^T \int_\Omega \left| \frac{\partial p_\gamma}{\partial t} \right| \, dx dt \leq \int_0^T \int_\Omega \left( \left| \frac{\partial p_\gamma}{\partial x} \right|^2 + \gamma p_\gamma |w_\gamma| \right) \, dx dt \leq C.$$

Thanks to the compactness assumption, we have the required bound:

$$\int_0^T \int_\Omega (|\partial_t p_\gamma| + |\partial_x p_\gamma|) \, dx dt \leq C, \tag{35}$$

from which strong convergence in  $L^1(Q_T)$  follows. Note that this convergence holds even pointwise after possibly passing to another sub-sequence. Finally, since  $p_\gamma \leq P_H$ , this bound also holds at the limit.  $\square$

**Theorem 4.2.** (Complementarity formula) *We may pass to the limit  $(\varepsilon, \gamma) \rightarrow (0, +\infty)$  in Eq. (16) to obtain the complementarity relation in the distributional sense, i.e.,*

$$p_\infty \left[ \frac{\partial^2 p_\infty}{\partial x^2} + n_\infty^{(1)} F(p_\infty) + n_\infty^{(2)} G(p_\infty) \right] = 0. \tag{36}$$

Here the  $n_\infty^{(i)}$  are strong  $L^1(Q_T)$ -limits of  $n_{\gamma,\varepsilon}^{(i)}$ ,  $i = 1, 2$ , and jointly with  $p_\infty$  they weakly satisfy the equations

$$\begin{cases} \frac{\partial n_\infty^{(1)}}{\partial t} = \frac{\partial}{\partial x} \left( n_\infty^{(1)} \frac{\partial p_\infty}{\partial x} \right) + n_\infty^{(1)} F_1(p_\infty) + n_\infty^{(2)} G_1(p_\infty), \\ \frac{\partial n_\infty^{(2)}}{\partial t} = \frac{\partial}{\partial x} \left( n_\infty^{(2)} \frac{\partial p_\infty}{\partial x} \right) + n_\infty^{(1)} F_2(p_\infty) + n_\infty^{(2)} G_2(p_\infty), \\ 0 = p_\infty (1 - n_\infty) \quad a.e., \end{cases} \tag{37}$$

starting from  $n_\infty^{(i)}(0) = n_{\infty,\text{init}}^{(i)}$ ,  $i = 1, 2$ , where  $n_\infty = n_\infty^{(1)} + n_\infty^{(2)}$ .

Before we begin the proof of the complementarity formula in the incompressible limit, we recall some properties of mollifiers and convolutions.

**Remark 3.** (Properties of mollifiers) We set

$$\varphi(x) := \begin{cases} 0, & |x| \geq 1, \\ M \exp\left(-\frac{1}{1-|x|^2}\right), & |x| < 1, \end{cases}$$

and recall that  $\varphi \in C_c^\infty(\mathbb{R})$  is a nonnegative, symmetric function. We choose  $M$  so that  $\varphi$  has mass one. Furthermore, we define the Dirac sequence  $(\varphi_\delta)_{\delta>0}$  by

$$\varphi_\delta(x) = \delta^{-1} \varphi(\delta^{-1}x).$$

Then, it holds that, for any function  $f \in W^{1,q}(\Omega)$  (with  $K := \int_{\mathbb{R}} |x|\varphi(x) dx$ ),

$$\|f * \varphi_\delta - f\|_{L^q(\Omega)} \leq K \|f'\|_{L^q(\Omega)} \delta.$$

Moreover, the derivative is given by

$$\varphi'_\delta(x) = -2 \frac{\delta^{-1}x}{[1 - (\delta^{-1}x)^2]^2} \varphi_\delta(x),$$

whence  $\|\varphi_\delta(x)\|_{L^1(\Omega)} \leq C\delta^{-1}$ .

We have now gathered all information necessary for passing to the limit in the pressure equation, Eq. (16).

**Proof.** We rewrite the equation for  $p_\gamma$  and multiply by a test function in order to obtain

$$\frac{1}{\gamma} \int_0^T \int_\Omega \phi(t, x) \left( \frac{\partial p_\gamma}{\partial t} - \left| \frac{\partial p_\gamma}{\partial x} \right|^2 \right) dx dt = \int_0^T \int_\Omega \phi(t, x) p_\gamma w_\gamma dx dt. \tag{38}$$

From the bounds

$$\int_0^T \int_\Omega \left| \frac{\partial p_\gamma}{\partial t} \right| dx dt \leq C, \quad \text{and} \quad \int_0^T \int_\Omega \left| \frac{\partial p_\gamma}{\partial x} \right|^2 dx dt \leq C,$$

the left-hand side of Eq. (38) must converge to zero, meaning that

$$p_\gamma w_\gamma \longrightarrow 0, \tag{39}$$

in the distributional sense. It now remains to identify the limit. To this end we write

$$\begin{aligned} \int_0^T \int_\Omega \phi p_\gamma w_\gamma dx dt &= \int_0^T \int_\Omega \phi p_\gamma \frac{\partial^2 p_\gamma}{\partial x^2} dx dt \\ &+ \int_0^T \int_\Omega \phi p_\gamma \left( c_\gamma^{(1)} F(p_\gamma) + c_\gamma^{(2)} G(p_\gamma) \right) dx dt, \end{aligned}$$

and we treat both terms independently.

*First term.* For the first one, we write

$$p_\gamma \frac{\partial^2 p_\gamma}{\partial x^2} = \frac{1}{2} \frac{\partial^2 p_\gamma^2}{\partial x^2} - \left( \frac{\partial p_\gamma}{\partial x} \right)^2,$$

leading to

$$\int_0^T \int_\Omega \phi p_\gamma \frac{\partial^2 p_\gamma}{\partial x^2} dx dt = \frac{1}{2} \int_0^T \int_\Omega \frac{\partial^2 \phi}{\partial x^2} p_\gamma^2 dx dt - \int_0^T \int_\Omega \phi \left| \frac{\partial p_\gamma}{\partial x} \right|^2 dx dt.$$

We may pass to the limit in the first term by Theorem 4.1. The second term requires to analyse compactness for  $\frac{\partial p_\gamma}{\partial x}$ , a problem we again approach with the Fréchet-Kolmogorov theorem as the main tool; its space derivative is already controlled since, from Corollary 1,

$$\sup_{0 \leq t \leq T} \left\| \frac{\partial^2 p_\gamma}{\partial x^2}(t) \right\|_{L^1(\Omega)} \leq C.$$

For the time derivative we will use the Fréchet-Kolmogorov compactness method, we shall prove that, as  $h$  and tends to 0,

$$\int_0^{T-h} \int_\Omega \left| \frac{\partial p_\gamma}{\partial x}(t+h, x) - \frac{\partial p_\gamma}{\partial x}(t, x) \right| dx dt \rightarrow 0.$$

Let us continue with the analysis. For the ease of notations, we set

$$u_h(t, x) := \frac{\partial p_\gamma}{\partial x}(t+h, x) - \frac{\partial p_\gamma}{\partial x}(t, x).$$

By comparing  $u$  to its mollified version, the triangular equality yields

$$\begin{aligned} \int_0^{T-h} \int_\Omega |u_h(t, x)| dx dt &\leq \int_0^{T-h} \int_\Omega |u_h(t, x) - u_h(t, \cdot) * \varphi_\delta(x)| dx dt \\ &\quad + \int_0^{T-h} \int_\Omega |u_h(t, \cdot) * \varphi_\delta(x)| dx dt. \end{aligned} \tag{40}$$

Here,  $\delta$  is a function (to be specified later on) of  $h$  tending to 0. By Remark 3, it holds that

$$\begin{aligned} &\int_0^{T-h} \int_\Omega |u_h(t, x) - u_h(t, \cdot) * \varphi_\delta(x)| dx dt \\ &\leq Ch \int_0^{T-h} \left\| \frac{\partial^2 p_\gamma}{\partial x^2}(t+h) - \frac{\partial^2 p_\gamma}{\partial x^2}(t) \right\|_{L^1(\Omega)} dt \leq Ch, \end{aligned}$$

thanks to Corollary 1. which proves that the right-hand side converges to zero as  $\delta \rightarrow 0$ , uniformly in  $\gamma$ . It suffices to show that the same result holds for the second integral. We write

$$\int_0^{T-h} \int_\Omega |u_h(t, \cdot) * \varphi_\delta(x)| dx dt \leq \int_0^{T-h} \int_\Omega |(p_\gamma(t+h) - p_\gamma(t)) * \varphi'_\delta(x)| dx dt,$$

after exchanging derivatives in the convolution. We now bound with the estimate on the derivative of the mollifier, cf. Remark 3:

$$\begin{aligned} & \int_0^{T-h} \int_{\Omega} |u_h(t, \cdot) * \varphi_{\delta}| dx dt \\ & \leq \int_0^{T-h} \int_{\Omega} |\varphi'_{\delta}(y)| dy \int_{\Omega} |p_{\gamma}(t+h, x) - p_{\gamma}(t, x)| dx dt \\ & \leq \frac{C}{\delta} \int_0^{T-h} \int_{\Omega} |p_{\gamma}(t+h, x) - p_{\gamma}(t, x)| dx dt \\ & \leq \frac{C}{\delta} \int_0^{T-h} \int_{\Omega} \left| \int_t^{t+h} \frac{\partial p_{\gamma}}{\partial t}(s, x) ds \right| dx dt. \end{aligned}$$

We rearrange the integrals and obtain

$$\begin{aligned} & \int_0^{T-h} \int_{\Omega} |u_h(t, \cdot) * \varphi_{\delta}| dx dt \\ & \leq \frac{C}{\delta} \int_{\Omega} \int_0^{T-h} \int_t^{t+h} \left| \frac{\partial p_{\gamma}}{\partial t}(s, x) \right| ds dx dt \\ & = \frac{C}{\delta} \int_{\Omega} \int_{s=0}^T \int_{t=\max(0, s-h)}^{\min(T-h, s)} \left| \frac{\partial p_{\gamma}}{\partial t}(s, x) \right| dt ds dx \\ & = \frac{C}{\delta} \int_{\Omega} \int_0^T (\min(T-h, s) - \max(0, s)) \left| \frac{\partial p_{\gamma}}{\partial t} \right| ds dx \\ & \leq \frac{Ch}{\delta} \int_{\Omega} \int_0^T \left| \frac{\partial p_{\gamma}}{\partial t}(s, x) \right| ds dx. \end{aligned}$$

Using the fact that  $\frac{\partial p_{\gamma}}{\partial t}$  is bounded in  $L^1(0, T; L^1(\Omega))$  uniformly in  $\gamma$ , cf. (35), we obtain

$$\int_0^{T-h} \int_{\Omega} |u_h(t, \cdot) * \varphi_{\delta}| dx dt \leq C\sqrt{h},$$

having set  $\delta = \sqrt{h}$ . Thus we conclude that the entire right-hand side of Eq. (40) converges to zero as  $h \rightarrow 0$ . Thus the time shifts are also controlled and we may infer the strong compactness of  $\frac{\partial p_{\gamma}}{\partial x}$ .

*Second term.* For the second term involving  $p_{\gamma}(c_{\gamma}^{(1)}F(p_{\gamma}) + c_{\gamma}^{(2)}G(p_{\gamma}))$ , we note that

$$p_{\gamma}(c_{\gamma}^{(1)}F(p_{\gamma}) + c_{\gamma}^{(2)}G(p_{\gamma})) = p_{\gamma}^{1-1/\gamma}(n_{\gamma}^{(1)}F(p_{\gamma}) + n_{\gamma}^{(2)}G(p_{\gamma})).$$

Passing to the limit requires weak convergence of  $n_{\gamma}^{(1)}$  and  $n_{\gamma}^{(2)}$ , since the strong convergence of the pressure would then allow us to pass to the limit in the second term, i.e.,

$$\begin{aligned} & \int_0^T \int_{\Omega} \phi p_{\gamma} \left( c_{\gamma}^{(1)} F(p_{\gamma}) + c_{\gamma}^{(2)} G(p_{\gamma}) \right) dx \\ & \rightarrow \int_0^T \int_{\Omega} \phi p_{\infty} \left( n_{\infty}^{(1)} F(p_{\infty}) + n_{\infty}^{(2)} G(p_{\infty}) \right) dx. \end{aligned}$$

While weak convergence of the individual species is sufficient for passing to the limit in the second term, we shall prove here strong  $L^1$ -compactness of the two species,  $n_{\gamma}^{(i)}$ ,  $i = 1, 2$ , since strong convergence is required in the segregation result below. In order to establish the strong compactness of  $n_{\gamma}^{(1)}, n_{\gamma}^{(2)}$ , we use the Fréchet-Kolmogorov theorem. For the space derivative, the result is already provided by estimate (22). For the time derivative, it suffices to use the equation for the  $n_{\gamma}^{(i)}$ 's. We focus on  $n_{\gamma}^{(1)}$  and expand the divergence term to get

$$\frac{\partial n_{\gamma}^{(1)}}{\partial t} = \frac{\partial n_{\gamma}^{(1)}}{\partial x} \frac{\partial p_{\gamma}}{\partial x} + n_{\gamma}^{(1)} \frac{\partial^2 p_{\gamma}}{\partial x^2} + n_{\gamma}^{(1)} F_1(p_{\gamma}) + n_{\gamma}^{(2)} G_1(p_{\gamma}).$$

The two last terms are in  $L^{\infty}(\Omega)$  while the two first terms are controlled in  $L^1(\Omega)$  thanks to Corollary 1. Consequently, we have strong convergence of the densities  $(n_{\gamma}^{(1)}, n_{\gamma}^{(2)})$  to some  $(n_{\infty}^{(1)}, n_{\infty}^{(2)})$  in  $L^1(Q_T)$ .

*Limit equation for  $n_{\infty}^{(1)}, n_{\infty}^{(2)}$ .* We aim at passing to the limit in

$$\frac{\partial n_{\gamma}^{(1)}}{\partial t} = \frac{\partial}{\partial x} \left( n_{\gamma}^{(1)} \frac{\partial p_{\gamma}}{\partial x} \right) + n_{\gamma}^{(1)} F_1(p_{\gamma}) + n_{\gamma}^{(2)} G_1(p_{\gamma}).$$

The reaction terms readily pass to the limit since  $p_{\gamma}$  converges strongly and the  $n_{\gamma}^{(i)}$ 's also. For the divergence term, we use the same results and the strong convergence of  $\frac{\partial p_{\gamma}}{\partial x}$  established above.

*Initial condition.* The limit Cauchy problem is completely identified with the initial condition  $n_{\infty, \text{init}}^{(1)}, n_{\infty, \text{init}}^{(2)}$ , thanks to (9).

*Other relations.* Equation (37) is obtained by writing  $n_{\gamma} p_{\gamma}^{\frac{\gamma-1}{\gamma}} = p_{\gamma}$ , and using the convergences of  $p_{\gamma}$  and  $n_{\gamma}$ , respectively, to conclude.

Note that similar arguments allow to prove the strong convergence of  $c_{\gamma}^{(1)}, c_{\gamma}^{(2)}$  to some  $c_{\infty}^{(1)}, c_{\infty}^{(2)}$ . These limits will satisfy the relations

$$c_{\infty}^{(i)} n_{\infty} = n_{\infty}^{(i)}, \quad c_{\infty}^{(i)} p_{\infty} = n_{\infty}^{(i)} p_{\infty}, \quad i = 1, 2.$$

□

**Remark 4.** We again emphasise that the solutions of the regularised system converge to those of the original one as  $\varepsilon$  tends to 0. This proves that the limit system obtained by letting both  $\varepsilon$  tend to 0 and  $\gamma$  tend to  $+\infty$  is also the system obtained from the original one by letting  $\gamma$  tend to  $+\infty$ .

### 5. Segregation Property

In order to establish the preservation of the segregation property  $n^{(1)}n^{(2)} \equiv 0$ , we begin with extracting subsequences such that the initial population fractions pass to the limit  $\gamma \rightarrow \infty, \varepsilon \rightarrow 0$ . More precisely, we notice that upon extracting subsequences, there exist  $c_{\infty,init}^{(1)}, c_{\infty,init}^{(2)} \in L^1(\Omega_0)$  such that, as  $\varepsilon \rightarrow 0, \gamma \rightarrow \infty$ ,

$$c_{\gamma,\varepsilon}^{(i)}(0) \rightarrow c_{\infty,init}^{(i)} \quad \text{in } L^1(\Omega_0). \tag{41}$$

Indeed, Helly’s selection theorem applies since the quotients are bounded both in  $L^\infty$  and in BV by assumption (11).

Our approach is then based on the observation that, in the absence of cross-reactions ( $F_2 = G_1 = 0$ ), a direct manipulation shows that  $n_\gamma c_\gamma^{(1)} c_\gamma^{(2)}$  satisfies the equation

$$\frac{\partial n_\gamma c_\gamma^{(1)} c_\gamma^{(2)}}{\partial t} = \frac{\partial}{\partial x} \left( n_\gamma c_\gamma^{(1)} c_\gamma^{(2)} \frac{\partial p_\gamma}{\partial x} \right) + n_\gamma c_\gamma^{(1)} c_\gamma^{(2)} \left( c_\gamma^{(2)} F_1(p_\gamma) + c_\gamma^{(1)} G_2(p_\gamma) \right). \tag{42}$$

If initially  $n_\gamma c_\gamma^{(1)} c_\gamma^{(2)} = 0$ , any weak solution will propagate the segregation property. We explain below that we can pass to the limit in this equation in the weak sense.

**Theorem 5.1.** (Segregation property for  $n_\infty^{(1)}, n_\infty^{(2)}$ ) *Under the assumptions of Theorem 4.2 and in the absence of cross-reactions ( $F_2 = G_1 = 0$ ), equation (42) holds for the limits when  $\gamma \rightarrow \infty$ . The segregation property holds, i.e., with the notations of Theorem 4.2, if  $n_{\infty,init}^{(1)} n_{\infty,init}^{(2)} = 0$ , a.e. in  $\Omega_0$ , then  $n_\infty^{(1)}(t) n_\infty^{(2)}(t) = 0$  a.e. in  $Q_T$ .*

**Proof.** Firstly, we pass to the limit in Equation (42). Then, writing  $n_\gamma(0, \cdot) c_\gamma^{(1)}(0, \cdot) c_\gamma^{(2)}(0, \cdot) = n_\gamma^{(1)}(0, \cdot) c_\gamma^{(2)}(0, \cdot)$ , we can pass to the limit in the initial data since both terms are in  $L^\infty(\Omega_0)$  and have a limit in  $L^1(\Omega_0)$ .

Applying the convergence results in Theorem 1.1, we can also pass to the limit in the weak form of Equation (42), see (12). Therefore we obtain for  $u = n_\infty c_\infty^{(1)} c_\infty^{(2)}$ , the equation

$$\begin{cases} \frac{\partial u}{\partial t} = \frac{\partial}{\partial x} \left( u \frac{\partial p_\infty}{\partial x} \right) + u \left( c_\infty^{(2)} F_1(p_\infty) + c_\infty^{(1)} G_2(p_\infty) \right), \\ u(0, \cdot) = n_{\infty,init} c_{\infty,init}^{(1)} c_{\infty,init}^{(2)} \in L^1(\Omega_0). \end{cases} \tag{43}$$

Secondly, we wish to show that  $u(t, \cdot) = 0$  when  $u(0, \cdot) = 0$ . To do this, we use the definition of the weak form (12) with a compactly supported test function  $\phi(t, x)$  which takes the value 1 on  $Q_T$  and arrive at

$$\frac{d}{dt} \int_\Omega u(t, x) \phi(t, x) dx \leq \|c_\infty^{(2)} F_1(p_\infty) + c_\infty^{(1)} G_2(p_\infty)\|_\infty \int_\Omega u(t, x) \phi(t, x) dx.$$

Using Gronwall’s lemma, we conclude that  $\int_\Omega u(t, x) \phi(t, x) dx = \int_{Q_T} u(t, x) dx = 0$  and thus  $u \equiv 0$ .  $\square$

**Remark 5.** This proof of the segregation property can be adapted to more general solutions of (43) than those with compact support. Using test functions with a truncation parameter, we merely need  $u \geq 0$  be integrable and  $\frac{\partial p_\infty}{\partial x}$  be bounded.

**Remark 6.** The product  $v := n_\gamma^{(1)} n_\gamma^{(2)}$ , is not well adapted because it solves

$$\frac{\partial v}{\partial t} = \frac{\partial}{\partial x} \left( v \frac{\partial p_\gamma}{\partial x} \right) + v \left( F_1(p_\gamma) + G_2(p_\gamma) + \frac{\partial^2 p_\gamma}{\partial x^2} \right).$$

This is not a well defined equation in the limit, with the available regularity on  $p_\infty$ . Indeed,  $\frac{\partial^2 p_\gamma}{\partial x^2}$  is bounded in  $L^1$  but  $\frac{\partial^2 p_\infty}{\partial x^2}$  is just a measure at the limit [28]. In other words, one cannot hope to derive the segregation property from the above equation on  $v$ .

### 6. Conclusions and Open Questions

We have established the incompressible limit of the two-species system (1) in one space dimension. The mathematical interest arises from vacuum states which generate a free boundary described by a Hele–Shaw type system. Our approach is based on an extension of the Aronson–Bénilan estimates which we use in an  $L^1$  setting rather than using upper bounds as usually done. Any improvement in the method and the estimate itself could be of interest. There are three major difficulties to extend this estimate to higher dimension. Firstly, we work in BV as in [9]. Secondly, some exchanges of derivatives obtained by integration by parts cannot be performed in more than one dimension. Thirdly, we use that  $p_\gamma$  is Lipschitz continuous (using Sobolev injections) which is crucial in estimates such as (29).

Several extensions could be of interest but require new ideas. The question of the regularity theory for the free boundary is completely open and faces the difficulty of weak estimates compared to the one species case in [25]. Including drift terms is of interest in view of [10, 11, 26]. Also including different mobilities for the two species as in [19] is an open question.

### Appendix A. Energy

**Proposition 5.** Let  $H_1(p) := \int_0^p F(z) dz$  and  $H_2(p) := \int_0^p G(z) dz$  for  $p \geq 0$ . Then, the energy

$$\mathcal{E}(t) := \int_{\Omega} \left( \frac{1}{2} \left| \frac{\partial p_{\gamma, \varepsilon}}{\partial x} \right|^2 - c_{\gamma, \varepsilon}^{(1)} H_1(p_{\gamma, \varepsilon}) - c_{\gamma, \varepsilon}^{(2)} H_2(p_{\gamma, \varepsilon}) \right) dx$$

is such that, for a constant  $C$  independent of  $\gamma$  and  $\varepsilon$ ,

$$\mathcal{E}'(t) + \gamma \int_{\Omega} p_{\gamma, \varepsilon} w_{\gamma, \varepsilon}^2 dx \leq C. \tag{44}$$

**Proof.** Consider the equation for the pressure (16) and multiply by  $-\frac{\partial^2 p_{\gamma}}{\partial x^2}$ . Integration by parts yields

$$\frac{1}{2} \frac{d}{dt} \int_{\Omega} \left| \frac{\partial p_{\gamma}}{\partial x} \right|^2 dx + \gamma \int_{\Omega} p_{\gamma} \left| \frac{\partial^2 p_{\gamma}}{\partial x^2} \right|^2 dx + \gamma \int_{\Omega} p_{\gamma} \frac{\partial^2 p_{\gamma}}{\partial x^2} R dx = 0. \tag{45}$$

Moreover, using the equations for  $c_{\gamma}^{(1)}$  and  $c_{\gamma}^{(2)}$ , we compute

$$\begin{aligned} & \frac{\partial \left( c_{\gamma}^{(1)} H_1(p_{\gamma}) \right)}{\partial t} \\ &= H_1(p_{\gamma}) \left( \frac{\partial c_{\gamma}^{(1)}}{\partial x} \frac{\partial p_{\gamma}}{\partial x} + c_{\gamma}^{(1)} F_1(p_{\gamma}) + c_{\gamma}^{(2)} G_1(p_{\gamma}) \right. \\ & \quad \left. - (c_{\gamma}^{(1)})^2 F(p_{\gamma}) - c_{\gamma}^{(1)} c_{\gamma}^{(2)} G(p_{\gamma}) \right) \\ & \quad + c_{\gamma}^{(1)} F(p_{\gamma}) \left[ \left| \frac{\partial p_{\gamma}}{\partial x} \right|^2 + \gamma p_{\gamma} w_{\gamma} \right], \end{aligned} \tag{46}$$

and

$$\begin{aligned} & \frac{\partial \left( c_{\gamma}^{(2)} H_2(p_{\gamma}) \right)}{\partial t} \\ &= H_2(p_{\gamma}) \left( \frac{\partial c_{\gamma}^{(2)}}{\partial x} \frac{\partial p_{\gamma}}{\partial x} + c_{\gamma}^{(1)} F_2(p_{\gamma}) + c_{\gamma}^{(2)} G_2(p_{\gamma}) \right. \\ & \quad \left. - (c_{\gamma}^{(2)})^2 G(p_{\gamma}) - c_{\gamma}^{(1)} c_{\gamma}^{(2)} F(p_{\gamma}) \right) \\ & \quad + c_{\gamma}^{(2)} G(p_{\gamma}) \left[ \left| \frac{\partial p_{\gamma}}{\partial x} \right|^2 + \gamma p_{\gamma} w_{\gamma} \right]. \end{aligned} \tag{47}$$

Summing (45), (46) and (47), and using the uniform bounds for  $c_{\gamma}^{(1)}$ ,  $c_{\gamma}^{(2)}$  and the reaction terms, we get

$$\begin{aligned} & \frac{d}{dt} \int_{\Omega} \left( \frac{1}{2} \left| \frac{\partial p_{\gamma}}{\partial x} \right|^2 - c_{\gamma}^{(1)} H_1(p_{\gamma}) - c_{\gamma}^{(2)} H_2(p_{\gamma}) \right) dx + \gamma \int_{\Omega} p_{\gamma} w_{\gamma}^2 dx \leq \\ & C \int_{\Omega} \left[ \left| \frac{\partial p_{\gamma}}{\partial x} \right|^2 + \left| \frac{\partial p_{\gamma}}{\partial x} \right| \left( \left| \frac{\partial c_{\gamma}^{(1)}}{\partial x} \right| + \left| \frac{\partial c_{\gamma}^{(2)}}{\partial x} \right| \right) \right] dx. \end{aligned}$$

Theorem 3.1, together with the Hölder inequality and the Sobolev embeddings, yield the desired bound (44).  $\square$
